17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally 1 A read-while-write error occurred during a previous read
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections 1 A Single Bit Correction occurred during a previous read
19	Reserved, reset to 0.

Table 460. MCR field descriptions (continued)

Field	Description
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that if the flash is sealed, and the Test Mode Disable Seal is programmed, erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations (and erase operations if the flash is unsealed). The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled 1 UTest NVM address space is enabled for program/erase and main address space disabled
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. 0 Flash memory is executing a high voltage operation 1 Flash memory is not executing a high voltage operation
22 PEG	Program/Eraser Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation. PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. 0 Program or erase operation failed 1 Program or erase operation successful <i>Note: If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block.</i> <i>Note: If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation.</i>

Table 460. MCR field descriptions (continued)

Field	Description
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set 1 An interrupt request will be generated when the DONE flag is set
24 FERS	Factory Erase and Program FERS is used for erase and program operations to enable a faster operation. Factory Erase must be done following "Initial Factory Conditions All Temps" with respect to voltage conditions, write/erase cycling, and temperature which can be from –40 °C to 150 °C. After setting the ERS or PGM bit, but prior to setting EHV, FERS may be set to enable a Factory Erase or Program. FERS can be written only when ERS or PGM are high, but EHV is still low. Factory Erase may also be disabled by writing a location in the UTest NVM space. Address 0x0020 in the UTest NVM space will be checked at reset, and if programmed with data that contains at least one zero, a factory erase is not allowed, and FERS is locked. Writes attempted that violate the above cases will result in FERS remaining cleared. FERS is cleared on reset. 0Factor Erase and Program is disabled 1Factory Erase and Program is enabled
25–26	Reserved, reset to 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: – User mode read (ERS is low and UTE is low) – Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0Flash memory is not executing a program sequence 1Flash memory is executing a program sequence
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0Program sequence is not suspended 1Program sequence is suspended

Table 460. MCR field descriptions (continued)

Field	Description
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0Flash memory is not executing an erase sequence 1Flash memory is executing an erase sequence
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0Erase sequence is not suspended 1Erase sequence is suspended
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: – Erase (ERS = 1, ESUS = 0) – Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) – Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. 0Flash memory is not enabled to perform a high voltage operation 1Flash memory is enabled to perform a high voltage operation <i>Note: Aborting a high voltage operation leaves addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.</i>

Note: See [Section 35.3, “Functional Description](#) for information about simultaneous MCR register writes, and priority levels.

35.2.3.2 Alternate Module Configuration Register (MCRA)

The following field and bit descriptions fully define the MCRA register ([Figure 392](#)).

Note: A number of Alternate Module Configuration Register (MCRA) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in [Section 35.3](#), “Functional Description”.

Figure 392. MCRA Register

MCRA register functions are shown in [Table 461](#).

Table 461. MCRA field descriptions

Field	Description
	Reserved, reset to 0.
PEASa	Program Access Space PEASa is used to indicate which space is valid for program operations, either main array space or UTest NVM space for the Alternate program and erase interface. It should be noted that erase is not allowed to the UTest NVM space (even if unsealed with the Test Mode Disable Seal) through the alternate interface. If an interlock write is done to the UTest NVM space with ERSa set, PEASa will remain 0. See PEAS definition in the MCR register for more information (Table 460).
DONEa	State Machine Status DONEa indicates if the embedded flash memory is performing a high-voltage operation for the Alternate program and erase interface. See DONE definition in the MCR register for more information (Table 460).
PEGa	Program/Erase Good The PEGa bit indicates the completion status of the last flash memory program or erase sequence for which high-voltage operations were initiated for the Alternate program and erase interface. See PEG definition in the MCR register for more information (Table 460). It should be noted that in the event of a error on the alternate interface PEGa will clear, but the ADR register will not be updated with the failing location. The ADR register is only valid for main interface program or erase fails, and other fails noted in the ADR register.

Table 461. MCRA field descriptions (continued)

Field	Description
	Reserved, reset to 0.
PGMa	Program PGMa is used to set up embedded flash memory for a program operation for the Alternate program and erase interface. See PGM definition in the MCR register for more information (Table 460).
PSUSa	Program Suspend PSUSa is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state for the Alternate program and erase interface. See PSUS definition in the MCR register for more information (Table 460).
ERSa	Erase ERSa is used to set up embedded flash memory for an erase operation for the Alternate program and erase interface. See ERS definition in the MCR register for more information (Table 460).
ESUSa	Erase Suspend ESUSa is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state for the Alternate program and erase interface. See ESUS definition in the MCR register for more information (Table 460).
EHVa	Enable High Voltage The EHVa bit enables the embedded flash memory for a high-voltage program/erase operation for the Alternate program and erase interface. See EHV definition in the MCR register for more information (Table 460).

Note: See [Section 35.3, “Functional Description](#) for information about simultaneous MCRA register writes, and priority levels.

35.2.3.3 Extended Module Configuration Register (MCRE)

The following field and bit descriptions fully define the MCRE register ([Figure 393](#)).

Figure 393. MCRE Register

35.2.3.4 Lock 0 register (LOCK0)

The Lock 0 (LOCK0) register provides a means to protect blocks from being modified.

The following field and bit descriptions fully define the LOCK0 register ([Figure 394](#)).

Figure 394. LOCK0 register

LOCK0 register functions are as shown in [Table 463](#).

Table 463. LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended. 0 UTest NVM block is available to be programmed 1 UTest NVM block is locked and cannot be programmed
1	Reserved, reset to 0.

Table 463. LOCK0 field descriptions (continued)

Field	Description
2–15 LOWLOCK[13:0]	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

Table 463. LOCK0 field descriptions (continued)

Field	Description
16–31 MIDLOCK[15:0]	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

35.2.3.5 Lock 1 Register (LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Figure 395. LOCK1 Register

LOCK1 register functions are as shown in [Table 464](#).

Table 464. LOCK1 field descriptions

Field	Description
0–15	Reserved, reset to 0.
16–31 HIGHLOCK[15:0]	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the High Blocks starts at HIGHLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. HIGH Blocks exist in partitions 4 and 5. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. The reset state of the lock registers is affected by the alternate program and erase block select information. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

35.2.3.6 Lock 2 Register (LOCK2)

The Lock 2 (LOCK2) register provides a means to protect blocks from being modified.

The following field and bit descriptions fully define the LOCK2 register ([Figure 396](#)).

Figure 396. LOCK2 Register

LOCK2 register functions are as shown in [Table 465](#).

Table 465. LOCK2 field descriptions

Field	Description
0–31 256KLOCK[31:0]	256 KB Block Lock 256KLOCK has the same characteristics as LOWLOCK. Please see that description for more information. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

35.2.3.7 Lock 3 Register (LOCK3)

The Lock 3 (LOCK3) register provides a means to protect blocks from being modified.

The following field and bit descriptions fully define the LOCK3 register ([Figure 397](#)).

Figure 397. LOCK3 Register

Offset 0x001C												Access: User read/write

LOCK3 register functions are as shown in [Table 466](#).

Table 466. LOCK3 field descriptions

Field	Description
0–15	Reserved, reset to 0.
16–31 256KLOCK[47:32]	256 KB Block Lock 256KLOCK has the same characteristics as LOWLOCK. Please see that description for more information. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

35.2.3.8 Alternate Lock 0 Register (LOCK0a)

The Alternate Lock 0 (LOCK0a) register provides a means to protect blocks from being modified on the alternate program and erase interface.

The following field and bit descriptions fully define the LOCK0a register ([Figure 398](#)).

Figure 398. LOCK0a Register

LOCK0a register functions are as shown in [Table 467](#).

Table 467. LOCK0a field descriptions

Field	Description
TSLOCKa	Alternate UTest NVM Lock This bit is used to lock the UTest NVM block from programs on the alternate program and erase interface (erase protection is not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCKa register signifies that the UTest NVM block is locked for program on the alternate interface. A value of 0 in the TSLOCKa register signifies that the UTest NVM block is available to receive program pulses on the alternate interface. The TSLOCKa register is not writable once an interlock write is completed until DONEa is set at the completion of the requested operation. Likewise, TSLOCKa register is not writable if a high-voltage operation is suspended. The TSLOCKa bit may be written as a register. The default value of the TSLOCKa bits is locked. 0 The UTest NVM block is available to receive program pulses on the alternate interface 1 The UTest NVM block is locked for program on the alternate interface
	Reserved, reset to 0

Table 467. LOCK0a field descriptions (continued)

Field	Description
LOWLOCKa[13:0]	Alternate Low Block Lock This is the method to lock blocks for the alternate program and erase interface. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCKa[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONEa is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCKa bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCKa bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

Table 467. LOCK0a field descriptions (continued)

Field	Description
MIDLOCKa[15:0]	Alternate Mid Block Lock This is the method to lock blocks for the alternate program and erase interface. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCKa[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONEa is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCKa bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCKa bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

35.2.3.9 Alternate Lock 1 Register (LOCK1a)

The Alternate Lock 1 (LOCK1a) register provides a means to protect blocks from being modified on the alternate program and erase interface.

The following field and bit descriptions fully define the LOCK1a register ([Figure 399](#)).

Figure 399. LOCK1a Register

Table 468. LOCK1a field descriptions

Field	Description
	Reserved, reset to 0.
HIGHLOCKa[15:0]	Alternate High Block Lock This is the method to lock blocks for the alternate program and erase interface. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the High Blocks starts at HIGHLOCKa[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. HIGH Blocks exist in partitions 4 and 5. The lock register is not writable once an interlock write is completed until DONEa is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCKa bits is locked. By default, all blocks are in the main program and erase space, and the main lock registers will have full functionality, and no blocks are in the alternative program and erase space (and will be forced to locked). Once selected for the alternate interface, the blocks selected in the alternative lock register will be available for locking or unlocking. The corresponding lock register in the main interface will be forced to locked, and are not writeable. This enables blocks to be present in only one program and erase space (main or secondary). In the event that blocks are not present (due to configuration or total memory size), the LOCKa bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations 1 Block is locked and unavailable for program and erase operations

35.2.3.10 Select 0 Register (SEL0)

The Select 0 (SEL0) register provides a means to select blocks to be operated on during erase.

The following field and bit descriptions fully define the SEL0 register ([Figure 400](#)).

Figure 400. SEL0 Register

SEL0 register functions are as shown in [Table 469](#).

Table 469. SEL0 field descriptions

Field	Description
0–1	Reserved, reset to 0.
2–15 LOWSEL[13:0]	LOW Block Select A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Low Blocks starts at LOWSEL[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. LOWSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0The block is not selected 1The block is selected for erase

Table 469. SEL0 field descriptions (continued)

Field	Description
16–31 MIDSEL[15:0]	Mid Block Select A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Mid Blocks starts at MIDLSEL[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. Mid Blocks exist in partitions 2 and 3. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. MIDSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0The block is not selected 1The block is selected for erase

35.2.3.11 Select 1 Register (SEL1)

The Select 1 (SEL1) register provides a means to select blocks to be operated on during erase.

The following field and bit descriptions fully define the SEL1 register ([Figure 401](#)).

Figure 401. SEL1 Register

Offset 0x003C												Access: User read/write

SEL3 register functions are as shown in [Table 472](#).

Table 472. SEL3 field descriptions

Field	Description
0–15	Reserved, reset to 0.
16–31 256KSEL[47:32]	256 KB Block Select A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

35.2.3.14 Address Register (ADR)

The Address (ADR) register provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

The following field and bit descriptions fully define the ADR register ([Figure 404](#)).

Figure 404. ADR Register

Offset 0x0050																Access: User read/write													
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	ADDR													0	0	0													
W																													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0													

ADR register functions are as shown in [Table 473](#).

Table 473. ADR field descriptions

Field	Description
0 SAD	UTest NVM Address The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD register is not writable. 0 Address captured is from main array space 1 Address captured is from UTest NVM array space
1 aH	Address High region The aH bit qualifies the address field (ADDR) to the region of a16K, a32K, and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region 1 Address captured or to be accessed is from high address region
2 aM	Address Mid region The aM bit qualifies the address field (ADDR) to the region of a16K, a32K, and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from mid address region 1 Address captured or to be accessed is from mid address region
3 aL	Address Low region The aL bit qualifies the address field (ADDR) to the region of a16K, a32K, and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region 1 Address captured or to be accessed is from low address region
4 a256k	Address 256 KB region The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region 1 Address captured or to be accessed is from 256 KB region
4 a64k	Address 64 KB region The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region 1 Address captured or to be accessed is from 64 KB region
6 a32k	Address 32 KB region The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region 1 Address captured or to be accessed is from 32 KB region
7 a16k	Address 16 KB region The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region 1 Address captured or to be accessed is from 16 KB region

Table 473. ADR field descriptions

Field	Description
8–28 ADDR[23:3]	Address The ADR register provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31	Reserved, reset to 0.

35.2.3.15 User Test 0 Register (UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

The following field and bit descriptions fully define the UT0 register ([Figure 405](#)).

Figure 405. UT0 Register

Offset 0x0054												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

UT0 register functions are as shown in [Table 474](#).

Table 474. UT0 field descriptions

Field	Description
0 UTE	U-Test Enable This status bit indicates when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect a status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register.
1 SBCE	Single Bit Correction Enable SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged. 0 Single Bit Correction observation is disabled 1 Single Bit Correction observation is enabled
2–12	Reserved, reset to 0
13 CPR	Customer Programmable Read Voltage and Reference Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21	Reserved, reset to 0

Table 474. UT0 field descriptions (continued)

Field	Description
22 NAIBP	Next Array Integrity Break Point If AIBPE is set, NAIBP will be set when a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0 will enable the Array Integrity operation to be restarted after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 0 Array Integrity state machine is not currently at a break point 1 Array Integrity state machine is at a break point
23 AIBPE	Array Integrity Break Point Enable If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 0 Array Integrity breakpoints are not enabled 1 Array Integrity breakpoints are enabled during Array Integrity checks
24	Reserved, reset to 0
25 AISUS	Array Integrity Suspend AISUS enables a suspend of an array integrity operation. Array integrity may be suspended by setting AISUS, and resumed by clearing AISUS. AISUS can be written to a 1 only when AID is low. AISUS can be written to a 0 only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written. 0 Array integrity sequence not suspended 1 Array integrity sequence is suspended
26 MRE	Margin Read Enable MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 0 Margin reads are not enabled 1 Margin reads are enabled
27 MRV	Margin Read Value MRV selects the margin level that is being checked. The margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 0 Zero's margin reads are requested 1 One's margin reads are requested
28	Reserved, reset to 0
29 AIS	Array Integrity Sequence AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. 0 Array integrity sequence is proprietary sequence 1 Array integrity sequence is sequential

Table 474. UT0 field descriptions (continued)

Field	Description
30 AIE	Array Integrity Enable AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE remains at 1 when the Array Integrity Check, or Margin Read are suspended or are in a breakpoint, and cannot be cleared. AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled 1 Array integrity checks are enabled
31 AID	Array Integrity Done AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing 1 Array integrity check is done

35.2.3.16 User Multiple Input Signature Register

The Multiple Input Signature registers (UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9) provide a means to evaluate array integrity.

35.2.3.16.1 UM0 Register

The following field and bit descriptions fully define the UM0 register ([Figure 406](#)).

Figure 406. UM0 Register

MISR register functions are as shown in [Table 475](#).

Table 475. UM0 field descriptions

Field	Description
0–31 MISR[31:0]	The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. <i>Note: Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way.</i> The MISR register provides a means to calculate an MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^7 + x^6 + x^5 + x^4 + x^2 + 1$ The MISR is calculated by taking the previous MISR value and then exclusive ORing the new data. In addition the most significant bit (in this case MISR[288]), is then exclusive ORed into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2], and MISR[0]. The result of the exclusive OR is shifted left on each read. The MISR register is used in array integrity operations. If, during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size), then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

35.2.3.16.2 UM1 Register

The following field and bit descriptions fully define the UM1 register ([Figure 407](#)).

Figure 407. UM1 Register

OPP0 register functions are as shown in [Table 485](#).

Table 485. OPP0 field descriptions

Field	Description
0–1	Reserved, reset to 0.
2–15 LOWOPP[13:0]	Low Block Over-Program Protection A value of 1 in a bit of the Over-Program Protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Low Blocks starts at LOWOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The LOWOPP register is not writable, and is status only. The default value of the LOWOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming 0 The corresponding block is available to be over-programmed

Table 485. OPP0 field descriptions (continued)

Field	Description
16–31 MIDOPP[15:0]	Mid Block Over-Program Protection A value of 1 in a bit of the over-program protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the Mid Blocks starts at MIDOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The MIDOPP register is not writable, and is status only. The default value of the MIDOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming 0 The corresponding block is available to be over-programmed

35.2.3.18 Over-Program Protection 1 Register (OPP1)

The Over-Program Protection 1 (OPP1) register provides a means to protect blocks from being over-programmed. This register shows the status of the over-program protection status. For more information on Over-Program Protection see [Section 35.3.1.2.4, Over-program protection enable](#).

The following field and bit descriptions fully define the OPP1 register ([Figure 417](#)).

Figure 417. OPP1 Register

1. A reset value of “–” indicates that the value is set at the factory and can vary among different devices.

OPP1 register functions are as shown in [Table 486](#).

Table 486. OPP1 field descriptions

Field	Description
0–15	Reserved, reset to 0.
16–31 HIGHOPP[15:0]	High Block Over-Program Protection A value of 1 in a bit of the Over-Program Protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the High Blocks starts at HIGHOPP[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The HIGHOPP register is not writable, and is status only. The default value of the HIGHOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming 0 The corresponding block is available to be over-programmed

35.2.3.19 Over-Program Protection 2 Register (OPP2)

The Over-Program Protection 2 (OPP2) register provides a means to protect blocks from being over-programmed. This register shows the status of the over-program protection status. For more information on Over-Program Protection see [Section 35.3.1.2.4, Over-program protection enable](#).

The following field and bit descriptions fully define the OPP2 register ([Figure 418](#)).

Figure 418. OPP2 Register

1. A reset value of “–” indicates that the value is set at the factory and can vary among different devices.

OPP2 register functions are as shown in [Table 487](#).

Table 487. OPP2 field descriptions

Field	Description
0–31 256KOPP[31:0]	256K Block Over-Program Protection A value of 1 in a bit of the Over-Program Protection register signifies that the corresponding block is protected from over-programming. A value of 0 in the OPP register signifies that the corresponding block is available to be over-programmed. The block numbering for the 256 KB Blocks starts at 256KOPP[0] and continues until all blocks are accounted. The 256KOPP register is not writable, and is status only. The default value of the 256KOPP bits is not OPP. In the event that blocks are not present (due to configuration or total memory size), the OPP bits default not OPP, and will remain 0. 1 The corresponding block is protected from over-programming 0 The corresponding block is available to be over-programmed

35.2.3.20 Over-Program Protection 3 Register (OPP3)

The Over-Program Protection 3 (OPP3) register provides a means to protect blocks from being over-programmed. This register shows the status of the over-program protection status. For more information on Over-Program Protection see [Section 35.3.1.2.4, Over-program protection enable](#).

The following field and bit descriptions fully define the OPP3 register ([Figure 419](#)).

Figure 419. OPP3 Register

Test Mode Disable Check register functions are as shown in [Table 489](#).

Table 489. TMD field descriptions

Field	Description
0–31 0	The Test Mode Disable Check register is used as a location to provide a password challenge to unlock blocks selected to be sealed as part of the Test Mode Disable seal mechanism. Please see Section 35.2.1.2, Test Mode Disable Seal for more information. Writes to the register have no effect except for a password challenge. Reads to this register will always return 0. The register's reset value is 0.

35.3 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in the section [Section 35.2.3.1, "Module Configuration Register \(MCR\)"](#). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in [Table 490](#).

Table 490. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM

Table 490. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- Low Power mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

35.3.1 User mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed, or erased. The following subsections define all actions that may be performed in user mode.

35.3.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read, except when the embedded flash memory is in low power mode. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

Note: Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

Warning: Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] = 0) will result in the interlock write being ignored, and address and data will not be updated.

Note: Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See [Section 35.2.3.1, Module Configuration Register \(MCR\)](#) for more information.

35.3.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning: In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

Note: *If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail (MCR[PEG] = 0), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated at an Over-Program Protected block.*

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the MCR[PGM] bit from a 0 to a 1.

Note: *Ensure the block that contains the address to be programmed is unlocked.*

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the BIU Block Guide for information on the size of writes that are allowed.
3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step ⁽⁹⁾ to terminate.
5. Wait until the MCR[DONE] bit goes high.

Note: *Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.*

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step ⁽²⁾.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of

0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step eight of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning: Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

35.3.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

35.3.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

35.3.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in [Section 35.2.3.1, Module Configuration Register \(MCR\)](#). Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

Warning: Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will

respond by completing the operation with a fail code (MCR[PEG] = 0).

35.3.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

35.3.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset. This feature is valid for programs done on the main interface, and not valid for programs done on the alternate interface.

35.3.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

Note: Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed if sealed (since erase is not allowed in the UTest NVM space when sealed).
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step ⁽⁹⁾ to terminate.
5. Wait until the MCR[DONE] bit goes high.

Note: Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step ⁽²⁾.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored (except for alternate erase interface). The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

35.3.1.3.1 Erase software locking

Software locking affects erase operation. For details on this see [Section 35.3.1.2.1, "Program software locking"](#).

35.3.1.3.2 Erase hardware locking

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

35.3.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, providing the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program)

before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

Warning: In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.

Warning: Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0).

35.3.1.4 Alternate program and erase interface

A second interface is provided on the flash for program and erase operations. The intent is that a dedicated master can have private access to blocks through this interface.

The alternate interface includes an alternate MCR register and alternate lock registers. Any block in low, mid, or high address space may be accessible through the alternate interface. The UTest NVM Block is also accessible for program through the alternate interface. 256 KB sized blocks are not accessible through this interface.

The alternate interface supports programming of data sizes from one doubleword (64 bits) to four doublewords within a single page (256 bits). Within a page, up to eight words may be altered in a single program operation. It is recommended that programming operations through the alternate interface be from 64 bits to 256 bits, and be 64-bit aligned.

The alternate interface supports erasing a single block at a time with each erase operation.

As with the main interface, erase suspend, program suspend, and erase-suspended programs are supported.

Program and Erase times for the alternate interface are the same as the main interface when programs and erases are done in isolation. If main interface and alternate interface are being utilized simultaneously, bandwidth sharing is utilized.

Note: It is possible for the UTest NVM block to exist in both the main program interface and alternate program interface. In the event of a conflict the first interface to do the program to an address will get priority, and all other attempts after this will result in an OTP over-program failure (MCR[PEG] or MCRA[PEGa] being set to 0).

35.3.1.4.1 Alternate program interface

The programming procedure follows exactly the same flow as the main interface, except that only page programming is allowed. See section [35.3.1.2, "Program"](#) for more information on programming.

The alternate interface program is done at lower priority compared to the main interface. Based on the size of programming allowed, the main interface has a 4:1 ratio advantage over the alternate interface. Program operations are allowed to finish on the active interface prior to allowing the inactive interface to execute its operation. Suspend done on the active interface enable the inactive interface to begin its operation.

For alternate program while erase, there could be a latency of up to 5 ms in the program operation.

For more information on interaction between the alternate program interface and the main interface, see [Section 35.3.1.4.3, "Alternate interface performance"](#).

If the alternate interface is the only interface active, then normal program times may be expected.

35.3.1.4.2 Alternate erase interface

For erases done thru the alternate interface, the single block to be erased is selected based on the address that is received during the erase interlock write. Thus the Select registers are not valid for the alternate interface (step ⁽²⁾ of the erase flow in section [Section 35.3.1.3, Erase](#)), and the interlock write address is used (step ⁽³⁾ of the erase flow in section [Section 35.3.1.3, Erase](#)). All other features of the main interface apply to the alternate erase interface. The erase procedure is exactly the same as for the main interface. See section [Section 35.3.1.3, Erase](#) for more information on erase.

The alternate interface erase is done at lower priority compared to the main interface. The time-slice ratio between the two interfaces is 10:1, with 50 ms of time given to the main erase for every 5 ms of alternate interface. Suspend done on the active interface enable the inactive interface to begin its operation.

For alternate erase while program, there can be a latency of up to 5 ms in the main program time. Once the alternate erase is interrupted, it will remain interrupted for main programs for a fixed time of 50 ms, at which time the alternate erase will restart. It should be noted that multiple interruptions of the alternate erase will significantly increase the total erase time.

For alternate erase while erase, the main erase has priority and receives 50 ms of erase for every 5 ms of alternate erase. This may result in a significant increase in the erase time for the alternate interface, and a minor increase in erase time for the main interface.

For more information on interaction between the alternate erase interface and the main interface, see [Section 35.3.1.4.3, "Alternate interface performance"](#).

If the alternate interface is the only interface active, then normal erase times may be expected.

35.3.1.4.3 Alternate interface performance

[Table 491](#) highlights the interactions between the alternate interface and the main interface for program, erase, suspend, and idle conditions.

Table 491. Alternate program and erase characteristics

Alt PGM/ERS interface request	Main PGM/ERS interface request	Alt interface result on memory array	Main interface result on memory array
IDLE	IDLE	IDLE	IDLE
IDLE/SUS	PGM/ERS	IDLE/SUS	PGM/ERS
PGM/ERS	IDLE/SUS	PGM/ERS	IDLE/SUS
PGM	PGM	PGM	Priority PGM (up to 4:1)
PGM	ERS	PGM with latency of 5 ms	ERS (possible minimal increase to total ERS time)
ERS	PGM	ERS (significant increase in total ERS time expected)	Priority PGM (possible latency of 5 ms) Once PGM is granted, 50 ms time slice available for more programs
ERS	ERS	ERS (significant increase in total ERS time expected)	Priority ERS (10:1) (possible minor increase to total ERS time) 50 ms Main ERS for every 5 ms alternate ERS

35.3.2 Low Power mode

In Low Power mode, the embedded flash memory enables VDDF power gating, and disables circuits on the VFLASH domain. It is the lowest current mode for the flash memory. No reads from or writes to the embedded flash memory are possible when in Low Power mode. Most power dissipation is due to leakage in this mode.

Prior to entering Low Power Mode, it is required that all program, erase, and UTest operations be stopped prior to entering the mode. If Low Power mode is entered while an operation is suspended, entering Low Power mode will have the same effect as a reset during suspend.

When in Low Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

35.3.3 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

35.3.3.1 Array integrity self-check

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks. The data to be read is customer-specific — user code may be programmed into the flash memory and the correct MISR signature is calculated based on that code. Any random or nonrandom code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the system frequency being used. The array integrity check consists of the following sequence of events:

1. Enable UTest mode.
2. Select the block or blocks to be receive the array integrity check by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for array integrity check do not need to be unlocked.

Note: Unselected blocks are still read as part of the array integrity sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

Note: Blocks protected with the Test Mode Disable Seal are still read as part of the array integrity sequence. The resulting read on sealed blocks will not be captured in the MISR, however the Single Bit Correction, Double Bit Detection and breakpoints will still be honored.

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

Note: For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that AIS be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR UM0 thru UM9 with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, ensure that UT0[SBCE] is set.
6. Set the UT0[AIE] bit.
 - i) If desired, the array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and then continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers will contain a signature for the portion of the operation that was completed prior to the abort, and will not be deterministic. Prior to doing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.
 - j) If desired, the array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the flash may be done. Once [AID] goes high, UT0[AISUS] may be cleared to resume the array integrity sequence.

Note: User mode array reads requested during the array integrity test will be ignored, to ensure that the array integrity operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until the UT0[AID] bit goes high.
8. If breakpoints were enabled, check UT0[NAIBP], and if this is set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear MCR[SBC] or MCR[EER] bits. Then the operation may be resumed by clearing UT0[NAIBP]. Continue to wait until the UT0[AID] bit goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 through UM9) to ensure correct signature.

Note: Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit.

35.3.3.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin reads are done at a read margin level checking for erased bits or programmed bits encroaching on the nominal read level. User margin read is a self-timed event, and is independent of system clocks or wait states selected. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific, and user code may be programmed into the flash memory. Any random or non-random code is valid. Once the operation is completed, the margin read results can be checked by reading the MCR[EER] bit and the MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode.
2. Select the block or blocks to receive margin read check by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for margin read do not need to be unlocked.

Note: Unselected blocks are still read as part of the margin read sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks will not result in a faster margin read execution time.

Note: Blocks protected with the Test Mode Disable Seal are still read as part of the margin read sequence. The resulting read on sealed blocks will not be captured in the MISR, however the Single Bit Correction, Double Bit Detection and breakpoints will still be honored.

Note: It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

Note: For margin read checks of the flash memory, sequential addressing is recommended. Setting AIS to 0 is possible for Margin Reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR UM0 thru UM9 with desired values.
5. Ensure that the MCR[EER] and MCR[SBC] bits are cleared.
6. If you want to detect single bits during margin read, set UT0[SBCE] to 1.
7. Set the UT0[MRE] bit.
8. Set the UT0[MRV] bit to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Set the UT0[AIE] bit.

Note: User mode array reads requested during the margin read test will be ignored, to ensure that the margin read operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

Note: During Margin Read operations, with AID low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

10. Wait until the UT0[AID] bit goes high.
 - a) If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See [Section 35.3.3.1, "Array integrity self-check"](#) for more information.
11. Read values in the MISR registers (UM0 through UM9) to ensure correct signature.

Note: Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

12. Write a logic 0 to the UT0[AIE] bit.

35.4 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning: Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

36 Decorated Storage Memory Controller (DSMC)

36.1 Introduction

This section details hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called “*decorated storage*”. It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A “decoration” is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l [b, h, w] d{cb}x rT, rB, rA` where the data size specifier is defined as 8-bit (*b* = byte), 16-bit (*h* = halfword) or 32-bit (*w* = word), and the three register specifiers include *rT* as the destination target register, *rB* as the effective address and *rA* as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st [b, h, w] d{cb}x rS, rB, rA` where the same data size specifiers are used, and the three register specifiers are *rS* as the source data register, *rB* as the effective address and *rA* as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the *rB* register (hence the “*x*” mnemonic suffix, signaling an “indexed” addressing mode) and the decoration is specified by the *rA* register. The core transmits the contents of the *rA* register as the decoration value along with the access address (register *rB*) to the DSMC.

The decorated load and store instruction formats are shown in [Figure 421](#).

Figure 421. Power Architecture Decorated Load and Store Instruction Formats

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
stbdcx	0	1	1	1	1	1			rS				rA				rB				1	0	1	0	0	0	0	0	0	1	1	/
sthdcx	0	1	1	1	1	1			rS				rA				rB				1	0	1	0	1	0	0	0	0	1	1	/
stwdx	0	1	1	1	1	1			rS				rA				rB				1	0	1	1	0	0	0	0	0	1	1	/
stbdcbx	0	1	1	1	1	1			rS				rA				rB				1	0	1	0	0	0	0	0	0	1	0	/
sthdcbx	0	1	1	1	1	1			rS				rA				rB				1	0	1	0	1	0	0	0	0	1	0	/
stwdcbx	0	1	1	1	1	1			rS				rA				rB				1	0	1	1	0	0	0	0	0	1	0	/

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit “decoration”. The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (l [b, h, w] dcbx) and store (st [b, h, w] dcbx) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

36.2 DSMC Block Diagram

The following block diagram, [Figure 422](#), shows the basic datapaths for the ECC logic in the DSMC. On both the read data path (hrdata) and the write data path (hwdata) there is logic to detect an ECC error and correct the data. The circle with X inside represents an XOR operation. The ecc_hmatrix and ecc_detect blocks are coefficient matrixes based on the Hsiao ECC algorithm. Notice in the recalculation of the s_hwchckbit[7:0] that there is a read chckbit from the slave (hrchckbit), a zero padded result contribution, and a contribution from the hwchckbit from the master. The details of the DSMC bit field and other operations are not shown (represented by the DSMC Operation box).

Figure 422. DSMC Block Diagram

36.3 Decorated Stores: `st [b,h,w] d{cb}x rS, rB, rA`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>. <size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

36.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container

Figure 423. Decoration Format: BFINS

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	0	SRTBIT	0	0	0	BFW	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	
bfins.h	0	0	0	0	0	0	SRTBIT			0	0	BFW			-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	
bfins.w	0	0	0	0	0	SRTBIT				0	BFW					-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	

This command inserts a bit field defined by SRTBIT and BFW into the memory “container” defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read

if bfw == 0
    then bfw = container

if ((srtbit + bfw) <= container) // generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp & ~mask // modify
      | wdata & mask

mem[accessAddress, size] = tmp // memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field “xyz” into an 8-bit memory container, initially set to “abcd_efgh”. For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz_----,
    then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
    then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
    then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
    then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
    then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_xyz,
    then destination is "abcd_xyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
    then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
    then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

36.3.1.1 Compare-and-Store (CAST)

Figure 424. Decoration Format: CAST

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CD8							
cast.h	1	0	0	1	-	-	-	-	-	-	-	-	-	-	-	-	CD16															
cast.w	1	0	0	1	CD28																											

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size] // memory read

if (size == 8) // define compare_operand
    compare_operand = CD8
else if (size == 16)
    compare_operand = CD16
    else compare_operand = {0x0, CD28} // zero-filled data

if (tmp == compare_operand) // compare - "modify"
    mem[accessAddress, size] = wdata // memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

36.3.1.1.1 Logical AND (AND)

Figure 425. Decoration Format: AND

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
and. {b,h,w}	1	0	1	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata // modify
mem[accessAddress, size] = tmp // memory write
```

36.3.1.1.2 Logical OR (OR)

Figure 426. Decoration Format: OR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
or. {b,h,w}	1	1	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata // modify
mem[accessAddress, size] = tmp // memory write
```

36.3.1.1.3 Logical Exclusive-OR (XOR)

Figure 427. Decoration Format: XOR

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
xor. {b,h,w}	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata // modify
mem[accessAddress, size] = tmp // memory write
```

36.3.1.2 Decorated Loads: 1 [b, h, w] d {cb} x rT, rB, rA

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an “extract”) operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

36.3.1.2.1 Simple Load (SLD)

Figure 428. Decoration Format: SLD

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
sld. {b,h,w}	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

36.3.1.2.2 Registers-and-Memory Exchange (SWAP)

Figure 429. Decoration Format: SWAP

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
cast.b	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	WD8							
cast.h	0	1	0	1	-	-	-	-	-	-	-	-	-	-	-	-	WD16															
cast.w	0	1	0	1	WD28																											

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp = mem[accessAddress, size] // memory read
```

```
rdata = tmp // rT = rdata = tmp
```

```
if (size == 8) // store_operand - "modify"
```

```
    store_operand = WD8
```

```
else if (size == 16)
```

```
    store_operand = WD16
```

```
    else store_operand = {0x0, WD28} // zero-filled write data
```

```
mem[accessAddress, size] = store_operand // memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

36.3.1.2.3 Load-and-Set-1(Bit) (LAS1)

Figure 430. Decoration Format: LAS1

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	0	BIT		-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT				-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp  = mem[accessAddress, size] // memory read
rdata = tmp // rT = rdata = tmp
mask  = 1 << (container - bit - 1) // generate bit mask
tmp   = tmp | mask // modify
mem[accessAddress, size] = tmp // memory write
```

36.4 DSMC Timing Diagram

The following timing diagram, [Figure 431](#), shows a decorated load followed by a decorated store instruction which is then followed by a normal load instruction. Both decorated instructions are read-modify-write instructions and thus they take at least two cycles to execute. In the first cycle an ECC calculation is performed on the read data as well as the write data. Then in the second cycle of the decorated instruction the decorated operation is performed and if it is a decorated store, the result is merged with the read data and sent to the write data bus along with the recalculated ECC write chkbits.

Figure 431. DSMC Timing Diagram

36.5 DSMC Instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

37 Flash Memory Programming and Configuration

This chapter provides basic guidance on activities related to configuring and programming the embedded flash memory in the SPC57EM80xx microcontroller.

Multiple layers of protection are available to prevent unintended updates to flash contents and unauthorized reads and writes to flash contents. The protection mechanisms range from simple write-protect bits for individual flash blocks to four levels of 256-bit password read and/or write protection and configuration of flash memory blocks as One Time Programmable (OTP).

Additionally, the SPC57EM80xx microcontroller includes a tamper detection feature, debug port enable/disable, and the ability to disable the ability for the device to be put into factory test mode.

Factory test mode disable
Configurable One Time Programmable (OTP) flash protection
Configurable tamper detection (erase counter)
Debug port enable/disable
Secure read protection (one to four 256-bit passwords)
Configurable secure write protection (one to four 256-bit passwords)
non-secure write protection
Flash blocks must be explicitly selected for erase operations
Code and data

Figure 432. Flash memory protection layers

At the lowest layer of protection, all flash erase operations require the explicit selection of one or more blocks of flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured *write* protection for individual flash blocks.

Similarly, up to four levels of password-secured *read* protection can be implemented. Unlike the password-secured write protection, which is implemented on a per-block basis, password-secured read protection applies to five pre-defined (at the factory) groups of flash blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

The SPC57EM80xx microcontroller also includes a tamper detection feature. In its most basic implementation, tamper detection acts as an erase counter. If tamper detection is implemented, a DCF record in the tamper detection *diary* must be written by software before a protected flash block can be erased. Multiple tamper detection regions can be defined by the customer, with each region containing one or more blocks. A block can be included in more than one tamper detection regions if desired.

Related to tamper detection is the ability to configure any flash block as OTP, so it can only be programmed once.

Finally, the microcontroller includes a feature that enables the customer to disable the device's ability to be placed in factory test mode.

The remainder of the chapter provides details these protection mechanisms and gives a brief overview of security configuration planning.

Note: Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the flash protection features work and relate to each other, please read the chapter in sequence, from beginning to end.

With the exception of read protection and tamper detection, which are applied to groups of flash memory blocks, access protection configuration is applied on a per-block basis, i.e., a custom level of access protection can be provided for each flash memory block. This is accomplished through the use of registers containing bits that are mapped to individual flash blocks. Understanding the mapping is key to understanding the implementation and use of the SPC57EM80xx microcontroller's flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in [Section 37.1, Selection of flash memory blocks for erase](#). It is important to understand the topic before proceeding to other sections.

37.1 Selection of flash memory blocks for erase

The registers used for selecting flash blocks for erase operations are the flash control registers named LOCK0, LOCK1, and LOCK2. There is also a LOCK3 register, but no flash blocks are mapped to it.

The LOCK0–2 registers are 32-bit registers containing fields associated to a specific address space: low address space, mid address space, high address space, or 256 KB address space. Each non-reserved bit in the fields is mapped to a specific flash block.

For example, [Figure 433](#) shows the flash module's Select 0 (SEL0) register. This register provides a way to select blocks in the low- and mid address spaces for erase operations.

Figure 433. SEL0 flash control register

Offset 0x0038												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	LOWSEL[13:0]													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	MIDSEL[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 492 shows an example of a mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual flash blocks⁽ⁱ⁾. In this case, not all bits of the LOWSEL and MIDSEL fields are mapped—only LOWSEL bits 0–11 (register bits 15–4^(j)) and MIDSEL bits 0–2 are mapped. Before any mapped block can be erased, it must be selected by writing a '1' to its corresponding bit in one of the SEL n registers. See the device configuration chapter for the complete mapping.

Note: Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in Figure 433, all bits are reset to '0'. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Table 492. Sample low and mid address space flash block bit mapping

Start Address	End Address	Size (KB)	Partition	LOCK n (1) Register	LOCK n Register Field Bit	LOCK n DCF Record DATA Bit ⁽²⁾	Read Lock group (3)	Block No.	Description
0x0040_4000	0x0040_7FFF	16	0	LOCK0	LOWLOCK[0]	16	—	0	BAF ⁽⁴⁾
0x00FC_0000	0x00FC_3FFF	16	0	LOCK0	LOWLOCK[1]	17	1	1	Code Flash ⁽⁵⁾
0x00FC_4000	0x00FC_7FFF	16	0	LOCK0	LOWLOCK[2]	18	1	2	Code Flash ⁴
0x00FC_8000	0x00FC_BFFF	16	1	LOCK0	LOWLOCK[3]	19	1	3	Code Flash ⁴
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash ⁴
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

i. The table lists the LOWLOCK register field but the structure is identical to the LOWSEL field in Figure 433.

j. Register bits in Power Architecture-based microcontrollers are numbered with the most significant bit as 0. This is not necessarily the case with register field bit numbering. The field bit numbering shown in the figure has the least significant bit numbered as 0.

Table 492. Sample low and mid address space flash block bit mapping (continued)

Start Address	End Address	Size (KB)	Partition	LOCK _n (¹) Register	LOCK _n Register Field Bit	LOCK _n DCF Record DATA Bit(²)	Read Lock group (³)	Block No.	Description
0x00FD_0000	0x00FD_7FFF	32	0	LOCK0	LOWLOCK[6]	22	1	6	Code Flash
0x00FD_8000	0x00FD_FFFF	32	1	LOCK0	LOWLOCK[7]	23	1	7	Code Flash
0x00FE_0000	0x00FE_FFFF	64	0	LOCK0	LOWLOCK[8]	24	1	8	Code Flash
0x00FF_0000	0x00FF_FFFF	64	0	LOCK0	LOWLOCK[9]	25	1	9	Code Flash
0x0061_0000	0x0061_FFFF	64	1	LOCK0	LOWLOCK[10]	26	3	10	Secure Code
0x0062_0000	0x0062_FFFF	64	1	LOCK0	LOWLOCK[11]	27	3	11	Secure Code
—	—	—	—	—	—	—	—	—	—
0x0068_0000	0x0068_3FFF	16	2	LOCK0	MIDLOCK[0]	0	4	12	Secure Data
0x0068_4000	0x0068_7FFF	16	3	LOCK0	MIDLOCK[1]	1	4	13	Secure Data
—	—	—	—	—	—	—	—	—	—
0x0040_0000	0x0040_3FFF	16	0	LOCK0	TSLOCK	31	0	32	UTEST(⁶)

1. There are multiple sets of LOCK_n registers, i.e., the flash module's LOCK0—3 registers and PASS module's PASS_LOCK0—3_PG0—3, but all use the same mapping of register bits to flash blocks. The same mapping applies the flash module's SEL0—3 registers.
2. The DCF record DATA bit refers to the DATA[31:0] field contained in DCF records created during OEM configuration activities. The DCF records related to flash blocks are used to implement password-secured write protection, password-secured read protection, tamper detection, and debug port enable/disable as a permanent part of the device configuration.
3. The Read Lock group pertains to protecting code and data blocks from being read by debuggers. This type of protection is implemented using DCF records and the PASS_LOCK3_PG0—3 registers.
4. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.
5. This block is searched to determine the boot location (if it contains the boot header).
6. One time programmable.

Example 6 Selecting blocks for erase

Referring to [Table 492](#), writing the value 0x0030_0000 to the SEL0 register ([Figure 433](#)) selects the following blocks for erase:

Start Address	End Address	Size (KB)	Partition	LOCK _n Register	LOCK _n Register Field Bit	LOCK _n DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash ⁴
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

Note: The mappings of SEL_n register bits to flash blocks vary with different microcontrollers. See the flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the SPC57EM80xx microcontroller.

37.2 Non-secure write protection

Non-secure write protection refers to the chip's ability to lock individual flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is *not* associated with the built-in register protection (REG_PROT) feature included with many of the chip's modules. The non-secure write protection feature detailed here applies only to embedded flash memory.

Implementing non-secure write protection is almost identical to selecting specific flash blocks for an erase operation—the only difference is the register used. To provide non-secure write protection for a block, write a '1' to the corresponding mapped bit found in one of the LOCK0–2 flash control registers.

Note: As indicated by the reset values shown in [Figure 434](#), after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The same bit mapping that applies to the SEL0–3 registers also applies to the LOCK0–3 registers.

Offset 0x0010												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	TSLOCK	0	LOWLOCK													
W																
Reset	1	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	MIDLOCK															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Referring to [Table 492](#), writing the value 0x0030_0000 (same value used in [Example 6](#)) to the LOCK0 register ([Figure 434](#)) locks the following blocks (same blocks selected in [Example 6](#)) so they cannot be programmed or erased, even if selected for erase:

Start Address	End Address	Size (KB)	Partition	LOCK <i>n</i> Register	LOCK <i>n</i> Register Field Bit	LOCK <i>n</i> DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash ⁴
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in [Section 37.3, Secure write protection](#)). All other blocks mapped to bits in the LOCK0 *can* be programmed because their corresponding bits have been set to '0'.

Secure write protection refers to the chip's ability to implement up to four levels of 256-bit password-secured *write* protection for individual flash blocks. Use of this feature is optional but the default behavior of the SPC57EM80xx microcontroller is to apply secure write protection. If there is a need to *not* write-protect specific blocks, that needs to be configured by creating the appropriate DCF records.

Note that the *secure* write protection settings override the non-secure write protection detailed in [Section 37.2, Non-secure write protection](#).

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each flash block. The DCF records use a bit mapping scheme identical to the mapping in the flash module's `SELn` and `LOCKn` registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the `PASS_LOCK0_PGn`–`PASS_LOCK3_PGn` registers.

The `PASS_LOCK0_PGn`–`PASS_LOCK3_PGn` registers are four identical sets of registers contained in the PASS module—they distinguished by the `PGn` suffix. The `PGn` (Password Group *n*) suffix indicates the password required to unlock that set of registers. Password 0 unlocks `PASS_LOCK0_PG0`, `PASS_LOCK1_PG0`, `PASS_LOCK2_PG0`, and `PASS_LOCK3_PG0`. Similarly, the registers suffixed with `PG1` are unlocked by matching password 1, and so on.

The `PASS_LOCK0_PGn`–`PASS_LOCK3_PGn` register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding flash block.

Each set of registers contains the same mapping of bits to flash blocks as the flash module's `SELn` and `LOCKn` registers. In any of the four `PASS_LOCKx_PGn` register sets, if a mapped bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one `PASS_LOCKx_PGn` register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

[Figure 435](#) shows how the registers interact. Note that secure write protection is only affected by the settings in `PASS_LOCK0_PGn`–`PASS_LOCK2_PGn`. The `PASS_LOCK3_PGn` registers have additional security functions, discussed in later topics.

Figure 435. Secure write protection

The next sections discuss implementing secure write protection and overriding secure write protection.

37.3.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PGn–PASS_LOCK2_PGn registers^(k). The DCF records have a structure that includes the same mapping of bits to flash memory blocks as the flash module's SELn and LOCKn registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PGn–PASS_LOCK2_PGn registers.

See [Chapter 9: Device Configuration Format \(DCF\) Records](#) for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to flash memory blocks is identical to the mapping used for selecting flash blocks for erase or non-secure write locking, there are two significant differences:

k. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

1. Configuring flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

Caution: Careful planning is required before writing DCF records. They are created in a write-once area of flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of DCF client list table ([Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#)). Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PGn–PASS_LOCK3_PGn registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTest flash memory. The structure of a DCF Record is shown in [Figure 436](#).

Figure 436. DCF record structure

Note: The values in the PASS_LOCKxPGn registers override the settings in the flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase.

The PASS_LOCKxPGn bits take effect when the life cycle is matured to "OEM Production" or older.

Example 8 Implementing secure write protection

Implementation of secure write protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) must be stored in a protected OTP area of device flash called UTest flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PGn–PASS_LOCK3_PGn) that have the same mapping of

register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers.

- DCF records must be created to define which flash memory blocks are to be locked and which blocks are not locked.

The records defined in step ⁽²⁾, determine the reset values of the PASS_LOCK0_PGn–PASS_LOCK3_PGn registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group:

Start Address	End Address	Size (KB)	Partition	LOCKn Register	LOCKn Register Field Bit	LOCKn DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash ⁴
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

From the PASS section of [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#):

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to [Figure 436](#), the values for the DCF record are:

- Data[31:0] is 0x0030_0000 (bits 0–31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47–61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0 (see footnotes in [Figure 437](#)).

The following DCF record provides secure write protection for the blocks in [Table 492](#) by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Figure 437. Sample DCF record for secure write protection

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	X (1)	X (2)

1. Bit 62 indicates parity strategy, which is not used in the PASS DCF records so it is a "don't care".
2. Bit 63 indicates whether the current record is the last DCF. Generally, this should be written as '0' so the first unprogrammed (all 1's) DCF record acts as the stop record.

The remaining blocks mapped to the PASS_LOCK0_PGn registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to flash blocks 4 and 5 set to '1'.

Caution: The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

See the PASS section of DCF client list table ([Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#)) for details on the DCF records.

37.3.2 Overriding secure write protection

The "PGn" (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the flash module's SEL0–2 registers and LOCK0–2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PGn registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to '1' in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to '0' in any of the registers makes the corresponding block available for programming or erase.

If a bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to '0'. If the same bit is set to '1' in more than one of the PASS_LOCKxPGn register sets, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

[Figure 438](#) shows the PASS_LOCK0_PGn register. As you can see, it has the same structure as the flash module's LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCKx_PGn registers and the flash LOCKn registers is how the reset values are determined.

By default, all mapped bits are set to '1', locking their corresponding flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

Figure 438. LOCK0_PGn register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'

Note: The values in the PASS_LOCKxPGn registers override the settings in the flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection. The PASS_LOCKxPGn bits take effect after the life cycle is matured to "OEM Production" or older.

Example 9 Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCKx_PGn registers, so the reset value for each mapped bit defaults to '1', causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCKx_PGn registers override the settings in the flash module's LOCK0–3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module's LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to '0' to make the desired flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CINn) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1–3.

Just as in previous examples, the result is the following blocks are available for program and erase operations but at a much higher level of security.

Start Address	End Address	Size (KB)	Partition	LOCK n Register	LOCK n Register Field Bit	LOCK n DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash ⁴
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

37.4 Secure read protection

Read Protection is ability of the flash controller to block read accesses to the flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool
- DMA reads
- SIPI reads
- All other types of bus master reads

When secure read protection is active, the affected flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a flash read protected region terminates with a bus error.

Most instances of flash memory read protection in the SPC57EM80xx microcontroller are *not* configurable by the customer. An example of this is the 256-bit passwords stored in UTest flash memory. Password-based read protection *is* customer-configurable⁽¹⁾ and is similar to the password-based write protection mechanism detailed in [Section 37.3, Secure write protection](#).

There are two significant differences between password-based read protection and password-based write protection in the SPC57EM80xx microcontroller.

1. Read protection can only be applied to pre-defined groups of flash memory blocks. These groups, called "Read Lock groups", cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to "Failure Analysis".

1. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

Another difference is that only the PASS_LOCK3_PGn register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

Note: The mappings of PASS_LOCK3_PGn register bits to flash blocks vary with different microcontrollers. See the flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the SPC57EM80xx microcontroller.

The next sections discuss implementing secure read protection and overriding secure write protection.

37.4.1 Implementing secure read protection

Implementation of secure read protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) are stored in a protected OTP area of device flash named UTest flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PGn–PASS_LOCK3_PGn) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.
2. DCF records must be created to define which flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PGn registers.
Like the other PASS_LOCKx_PGn registers, the PASS_LOCK3_PGn registers have two functions.
 - Reading the registers provides a lock status for each Read Locking group.
 - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PGn registers is shown in [Figure 439](#). The fields relevant to implementing secure read protection are RL4–RL0.

Figure 439. PASS_LOCK3_PGn Register

		0x010C LOCK3_PG0																			
		0x011C LOCK3_PG1

		0x013C LOCK3_PG3																			

Table 493. Sample low and mid address space flash block bit mapping (continued)

Start Address	End Address	Size (KB)	Partition	LOCK _n Register	LOCK _n Register Field Bit	LOCK _n DCF Record DATA Bit	Read Lock group	Block No.	Description
0x0061_0000	0x0061_FFFF	64	1	LOCK0	LOWLOCK[10]	26	3	10	Secure Code
0x0062_0000	0x0062_FFFF	64	1	LOCK0	LOWLOCK[11]	27	3	11	Secure Code
—	—	—	—	—	—	—	—	—	—
0x0068_0000	0x0068_3FFF	16	2	LOCK0	MIDLOCK[0]	0	4	12	Secure Data
0x0068_4000	0x0068_7FFF	16	3	LOCK0	MIDLOCK[1]	1	4	13	Secure Data
—	—	—	—	—	—	—	—	—	—
0x0040_0000	0x0040_3FFF	16	0	LOCK0	TSLOCK	31	0	32	UTEST

To provide two level of password protection for only Read Lock group 3 and leave all other groups unlocked, the RL3 bit can be set in any two of the four PASS_LOCK3_PG_n registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RL_n bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to [Figure 436](#), the values for the DCF record are:

- For LOCK3_PG0
 - Data[31:0] is 0x0008_0000 (bits 0–31)
 - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
 - Address[16:2] is 0b000_0000_0100_0011 (bits 47–61)
 - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
 - Preferred Stop value is 0.
- For LOCK3_PG1
 - Data[31:0] is 0x0008_0000 (bits 0–31)
 - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
 - Address[16:2] is 0b000_0000_0100_0111 (bits 47–61)
 - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
 - Preferred Stop value is 0.
- For LOCK3_PG2
 - Data[31:0] is 0x0000_0000 (bits 0–31)
 - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
 - Address[16:2] is 0b000_0000_0100_1011 (bits 47–61)
 - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
 - Preferred Stop value is 0.
- For LOCK3_PG3
 - Data[31:0] is 0x0000_0000 (bits 0–31)
 - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
 - Address[16:2] is 0b000_0000_0100_1111 (bits 47–61)
 - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
 - Preferred Stop value is 0.

37.4.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PG n registers (see [Figure 439](#)) contain five read protection fields, RP0–RP4, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG n [RL n] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to '1', causing the blocks associated with each read group to be read locked.

Example 11 Overriding secure read protection

Building on [Example 10](#), where Read Lock group 3 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL3 bit to '0' in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN n) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS_CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL3] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

37.5 Debug port enable/disable

The mechanism for temporarily enabling the SPC57EM80xx debug port after it has been locked by its life cycle state is similar to the flash memory read protection mechanism detailed in [Section 37.4, Secure read protection](#). The difference is that the PASS_LOCK3_PG n [DBL] field is used instead of the RP0–RP4 fields.

37.6 Tamper detection

The Tamper Detection Module (TDM) provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

This section provides details on the mapping between DCF record bits and individual flash memory blocks to be selected for tamper detection.

See [Chapter 85: Tamper Detection Module \(TDM\)](#), for details on tamper detection, including the DCF clients and two additional memory-mapped registers.

There are two significant differences between selecting blocks for tamper detection and selecting blocks for other activities, e.g., a flash erase operation:

1. Selection of blocks for tamper detection protection is done only during device configuration to customer specifications, either at the factory or by the customer during OEM production activities. The selection becomes a permanent part of the device configuration.
2. The selection of blocks for tamper detection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

The Tamper Detect section of DCF client list table ([Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#)) gives the CS and Address value combinations that correspond to groups of LOCK0–LOCK3 registers, similar to the flash module's LOCK0–LOCK3 registers.

The mapping of individual flash blocks to TDM DCF record data field bits is shown in included in the detailed flash block map in the flash section of the Device Configuration chapter.

37.6.1 Implementing tamper detection

Implementing tamper detection requires:

1. Creating the tamper detect diary
2. Assigning blocks to Tamper Detection Regions (TDRs)

The tasks are detailed in the following sections

37.6.2 Creating the tamper detect diary

Tamper detection in the SPC57EM80xx microcontroller is user-defined. The basic functionality provided is an erase counter, or diary, for 6 user-defined regions, called “tamper detect regions”, or TDRs, within the flash memory. Each TDR is defined using a set of DCF records that is similar in function and layout to the flash module's SEL n and LOCK n registers, which contain bits matched to specific flash blocks.

For a program or erase operation to be performed on a block included in a TDR, a record must be written to a “diary” that tracks flash modification operations. The format and size of records is customer-defined. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes.

Note: The limiting factor for tamper detection records is the diary size. The total diary size is given by the number of TDRs (6 for SPC57EM80xx) multiplied by 2 KB, the portion of the diary allotted to records associated with each TDR.

Since the minimum flash programming operation size is 8 bytes, the maximum number of tamper detect records for a given TDR is 256 8-byte entries.

The diary can be placed within any flash block in the flash array but to maintain the security of the TDR, there are two constraints:

- The block where the diary is placed must be assigned as OTP within the OTP registers (covered in the next section)
- The diary base address must be on a 4 KB boundary, therefore the least significant 12 bits of the base address must all be '0'

Warning: The tamper detect diary base address DCF record is a “write once” record. All subsequent tamper detect diary base address DCF records created are ignored.

Example 12 Creating the tamper detect diary

If the total space required for a diary is 12 KB (as in the case of 6 TDRs), any flash block can be used because the smallest flash blocks in the SPC57EM80xx microcontroller are 16 KB. Since the diary base address must be on a 4 KB boundary, though, if the diary base address is within a 16 KB flash block, it can only be assigned to the base address of the block or the address given by the base address plus 4 KB.

If the base address of the 16 KB block is 0x00FC4000, the base address of the diary is given by:

0b0000_0000_1111_1100_0000_0000_0000_0000 (16 KB base address)

or

0b0000_0000_1111_1100_0001_0000_0000_0000 (16 KB base address + 4 KB)

The base address of each TDR's section of the diary is:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

We need to create one DCF record that defines the base address for the diary. The information required is from the Tamper Detect section of [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0000	Diary Base Address

Referring to [Figure 436](#), the values for the DCF record are:

- For LOCK3_PG0
 - Data[31:0] is 0x00FC4000 (the base address)
 - CS[14:0] is 0b000_0000_0001_0000 (bits 32–46)
 - Address[16:2] is 0b000_0000_0000_0000 (bits 47–61)
 - Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
 - Preferred Stop value is 0.

See the Tamper Detect section of DCF client list table ([Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#)) for details.

Note: *User software must check whether the diary is full. If the diary area for a TDR is full, user software must program a DCF record to override blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry. This is detailed in [Section 37.6.4, Overriding tamper detection](#).*

37.6.3 Assigning blocks to Tamper Detection Regions (TDRs)

Tamper detection regions are defined by creating TDRx_LOCKn DCF records. For example, in a microcontroller with six tamper detection regions, the following records define the TDRs:

- TDR0_LOCK0, TDR0_LOCK1, TDR0_LOCK2, TDR0_LOCK3
- TDR1_LOCK0, TDR1_LOCK1, TDR1_LOCK2, TDR1_LOCK3
- TDR2_LOCK0, TDR2_LOCK1, TDR2_LOCK2, TDR2_LOCK3
- TDR3_LOCK0, TDR3_LOCK1, TDR3_LOCK2, TDR3_LOCK3
- TDR4_LOCK0, TDR4_LOCK1, TDR4_LOCK2, TDR4_LOCK3
- TDR5_LOCK0, TDR5_LOCK1, TDR5_LOCK2, TDR5_LOCK3

Each set of TDRxLOCKn DCF records mapped in exactly the same way as the flash module's SELn and LOCKn registers (see the detailed flash block map in the flash section of the Device Configuration chapter for the mapping).

In the TDRxLOCKn DCF records:

- A bit set to '1' means the corresponding flash block is assigned to this TDR
- A bit set to '0' means the corresponding flash block is NOT assigned to this TDR

The default state (no TDRs defined) is defined as 'Block NOT assigned to the TDR'.

37.6.4 Overriding tamper detection

When a TDR's diary section is full, a Tamper Override (TO) record must be created before a block assigned to the TDR can be programmed or erased.

The details of the data section of the DCF record used to override tamper detection is shown in [Figure 440](#).

Warning: Bits in this DCF record is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

Figure 440. Data portion of Tamper Region Override (TO) DCF record

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
W	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
W	0	0	0	0	0	0	0	0	0	0	TOE5	TOE4	TOE3	TOE2	TOE1	TOE0

Example 13 Implementing secure write protection

Assume the diary Tamper Detection Region 3 is full

We need to create one DCF record that defines that overrides tamper detection for the tamper detection region whose diary is full. The information required is from the Tamper Detect section of [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0001_0000	000_0000_0000_0001	Tamper Region Override

Referring to [Figure 436](#), the values for the DCF record are:

- Data[31:0] is 0x0000_0008 (TOE3)
- CS[14:0] is 0b000_0000_0001_0000 (bits 32–46)
- Address[16:2] is 0b000_0000_0000_0001 (bits 47–61)
- Parity value is irrelevant because it is not used in Tamper Detect DCF records (bit 62)
- Preferred Stop value is 0.

See the Tamper Detect section of DCF client list table ([Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#)) for details.

37.7 Implementing OTP

Any flash block within the flash array can be assigned, at any time, to be OTP. OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (i.e., flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

Warning: After a flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#). See the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

37.8 Implementing test mode disable

The SPC57EM80xx flash memory module includes a mechanism to disable manufacturer entry into test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method are able to have possible failures analyzed by manufacturer's failure analysts.

Test mode disable prevents all high voltage operations to the flash executed by the internal state-machine, as well as reads through the state machine, and reads through the Array Integrity state machine when using test mode interfaces.

Optionally, the customer can create a password to enable manufacturer entry into test mode.

37.8.1 Unconditional test mode disable seal

Warning: This process is not reversible. After completing these steps the SPC57EM80xx microcontroller is permanently prevented from entering test mode for factory analysis.

The steps for unconditionally disabling test mode are the same steps required for implementing passcode-protected entry into test mode with one exception—the passcode specified must be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To unconditionally disable test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTest flash memory map.
2. Program one of the three *invalid* passcodes shown above into the Test Mode Override Passcode area shown in the UTest flash memory map.
3. Program the value 0x2D3C_4B5A into the Test Mode Disable Seal location specified in the UTest flash memory map.

After the next reset is asserted, Test Mode is permanently disabled.

Note: *Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.*

The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

37.8.2 Passcode-protected test mode disable seal

The steps for implementing passcode-protected entry into test mode are the same required for unconditionally disabling test mode with the exception that —the passcode specified must NOT be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To implement passcode-protected test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTest flash memory map.
2. Program a valid passcode into the Test Mode Override Passcode area shown in the UTest flash memory map.
3. Program the value 0x2D3C_4B5A into the Test Mode Disable Seal location specified in the UTest flash memory map.

After the next reset is asserted, Test Mode is permanently passcode protected.

Note: *Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.*

The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

37.8.3 Selecting flash memory blocks for test mode disable seal

Selecting flash memory blocks for test mode disable seal protection is similar to selecting blocks for tamper detection in that it involves writing to non-register flash locations. In the case of the test mode disable seal function, there are two areas of UTest flash memory that have identical mapping to flash memory blocks. When the test mode disable seal takes effect, the mapped bits are logically ORed to determine the blocks to be protected.

Caution: The mapping of bits to blocks for this function is different from the mapping used for other functions. See the table in the device configuration chapter for the map.

Caution: Selecting a block for test mode disable requires a '0' in the mapped bit—not a '1' as with other functions.

The mapping of individual flash blocks to Test Mode Disable Block Select bits is shown in [Table 494](#).

Table 494. Mapping of Test Mode Disable Block Select bits to flash blocks

37.9 Security configuration planning

At minimum, designing the flash security framework consists of selecting the security features to be implemented and determining the scope of implementation for each selected feature.

In devices containing a hardware Security Module (HSM), significant planning must go into the implementation of HSM functions. The HSM is an independent software platform within the microcontroller. It is intended to be used to implement advanced security functions that are defined by customer software.

Note: Details of advanced security features, including the advanced security architecture and the Hardware Security Module (HSM) are contained in the SPC57EM80xx Microcontroller Security Reference Manual. Distribution of the document is restricted to qualified customers.

The basic security features available in the SPC57EM80xx microcontroller include:

- Secure write protection
- Secure read protection
- Debug port enable/disable
- One-time-programmable (OTP) flash memory block assignment
- Factory test mode disable

37.9.1 Hardware Security Module (HSM)

Details of the HSM are included in the *SPC57EM80xx Microcontroller Security Reference Manual*. It is mentioned here because the flash memory module includes blocks that can be configured for exclusive access by the HSM. If the HSM is to be used in an application it is advisable to protect HSM code by configuring it for exclusive access by the HSM. The blocks configurable for exclusive access by the HSM appear in [Figure 6](#) in [Chapter 3: Embedded memories](#). They are labeled as secure code flash or secure EEPROM emulation blocks. They are not configured for HSM-exclusive access by default, though—they are

available to act as secure flash areas but must be explicitly configured for that purpose. See the *SPC57EM80xx Microcontroller Security Reference Manual* for details.

37.9.2 Creating password groups

Most basic security features in the SPC57EM80xx microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTest memory map ([Table 16](#)) in [Chapter 5: Memory Map](#).

The UTest memory map fields to be written are:

- PASS Password Group 0
- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Passwords must not be one of the following, which are considered insecure and therefore invalid:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

Warning: The password fields are in OTP UTest flash, so they can only be written once.

37.9.3 Planning secure write protection

Up to four levels of password-secured write protection can be assigned to any block. Note that by default, all blocks of user flash are write protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured write protection. The write protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure write protection, please thoroughly review the implementation steps detailed in [Section 37.3.1, Implementing secure write protection](#) and [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

37.9.4 Planning secure read protection

Up to four levels of password-secured write protection can be assigned to flash blocks in pre-defined Read Locking groups. Note that by default, all blocks of user flash are read protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured read protection. The read protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure read protection, please thoroughly review the implementation steps detailed in [Section 37.4.1, Implementing secure read protection](#) and [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

37.9.5 Planning debug port enable/disable

Please see [Section 37.5, Debug port enable/disable](#) and [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

37.9.6 Planning OTP flash memory block assignment

Any block of user flash can be configured as OTP. The need to configure blocks as OTP will depend on the data or code to be stored in the block. It is important to note that configuring a flash block as OTP is not reversible.

Before creating DCF records to implemented OTP flash blocks, please thoroughly review the implementation steps detailed in [Section 37.7, Implementing OTP](#) and [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

37.9.7 Planning factory test mode disable

Please see [Section 37.8, Implementing test mode disable](#) and [Table 112](#) in [Chapter 9: Device Configuration Format \(DCF\) Records](#).

38 Analog-to-Digital Converters (ADC) Configuration

38.1 ADC overview

This chapter is organized into the following sections:

- [Section 38.1, ADC overview](#)
 - [Section 38.1.1, ADC subsystem block diagram](#)
 - [Section 38.1.2, Analog input pin multiplexing](#)
- [Section 38.2, Configuration of ADC modules](#)
 - [Section 38.2.1, Sigma-Delta Analog-to-Digital Converter \(SDADC\)](#)
 - [Section 38.2.2, Successive Approximation Register Analog-to-Digital Converter \(SARADC\)](#)

SPC57EM80xx contains the following analog-to-digital converters (ADCs):

- 8 independent 12-bit Successive Approximation Register Analog-to-Digital Converters (SARADCs)
- 6 independent 16-bit Sigma-Delta Analog-to-Digital Converters (Sigma-Delta, or SDADCs)

These ADCs interface to external analog input pins:

Number of external analog input pins	Package
48	QFP176
48	216 FusionQuad ED
60	BGA292

Each ADC instance, whether SAR or Sigma-Delta, has independent analog input pin multiplexing, register interface, trigger and clock inputs, independent interrupt, and DMA capability. Each SAR and Sigma-Delta ADC has a dedicated peripheral bridge (PBRIDGE) interface for CPU access to the registers.

All SAR and Sigma-Delta ADCs share the same supply pins (VDD_HV_ADV/VSS_HV_ADV) and ground, but have separate reference pins. This is true for all packages.

Note that for compatibility reasons, the SARADC numbering omits SARADC_5. The SARADC_s on the device are referred to as SARADC_B (60:1 input mux), SARADC_0–SARADC_4, SARADC_6, and SARADC_7 (maximum 8:1 input mux for each).

38.1.1 ADC subsystem block diagram

[Figure 441](#) gives the block diagram for the high-level integration of the ADC sub-system for SPC57EM80xx. The primary intent of the diagram is to show that each ADC, whether SAR or Sigma-Delta, have independent register interfaces, interrupt/DMA requests, and trigger source selection.

Figure 441. SPC57EM80xx ADC subsystem

38.1.2 Analog input pin multiplexing

There are 48 external analog input pins in the QFP176 package for SPC57EM80xx, and 60 in the BGA292 package. All analog input pins in either package are readable by SARADC_B. In addition to SARADC_B, most analog input pins are routed to either the Sigma-Delta or SARADC_s, but never both. [Table 495](#) gives the analog input pin assignment for both SPC57EM80xx QFP176 and 292 BGA packages.

Table 495. SPC57EM80xx analog input pin multiplexing

ADC instance	QFP176 (and 256 FusionQuad ED)		BGA292 (ED and PD)	
	Analog input pins	Mux input ⁽¹⁾	Analog input pins	Mux input ⁽¹⁾
SARADC_B	0:8, 10:13, 16:21, 24:29, 32:33, 35:39, 44:53, 56:61	0:8, 10:13, 16:21, 24:29, 32:33, 35:39, 44:53, 56:61	0:53, 56:61	0:53, 56:61
SARADC_0	AN4:AN7	4:7	AN4:AN7	4:7
SARADC_1	AN8, AN10:AN13	8, 10:13	AN8:AN15	8:15
SARADC_2	AN16:AN19	16:19	AN16:AN19, AN22, AN23	16:19, 22, 23
SARADC_3	AN26:AN29	26:29	AN26:AN31	26:31
SARADC_4	AN32:AN33, AN35	32:33, 35	AN32:AN35	32:35
SARADC_6	AN48:AN51	48:51	AN40:AN43, AN48:AN51	40:43, 48:51
SARADC_7	AN56:AN59	56:59	AN56:AN59	56:59
SDADC_0	AN2:AN3	AN[0]:AN[1]	AN2:AN3	AN[0]:AN[1]
SDADC_1	AN0:AN1	AN[0]:AN[1]	AN0:AN1	AN[0]:AN[1]
SDADC_2	AN20:AN21, AN24:AN25	AN[0]:AN[1], AN[2]:AN[3]	AN20:AN21, AN24:AN25	AN[0]:AN[1], AN[2]:AN[3]
SDADC_3	AN36:39, AN44:47	AN[0]:AN[7]	AN36:39, AN44:47	AN[0]:AN[7]
SDADC_4	AN52:AN53	AN[0]:AN[1]	AN52:AN53	AN[0]:AN[1]
SDADC_5	AN60:AN61	AN[0]:AN[1]	AN60:AN61	AN[0]:AN[1]

- For the Sigma-Delta mux inputs, even channel numbers (0,2,4,6) correspond to the positive terminal of the differential input, and odd channel numbers (1,3,5,7) correspond to the negative terminal.

38.2 Configuration of ADC modules

The following sections describe device-specific details for the following modules:

- [Section 38.2.1, Sigma-Delta Analog-to-Digital Converter \(SDADC\)](#)
- [Section 38.2.2, Successive Approximation Register Analog-to-Digital Converter \(SARADC\)](#)

38.2.1 Sigma-Delta Analog-to-Digital Converter (SDADC)

There are six independent Sigma-Delta ADCs on SPC57EM80xx. Refer to [Figure 441](#) for the ADC subsystem block diagram.

The following sections describe configuration details:

- [Section 38.2.1.1, Sigma-Delta ADC integration diagram](#)
- [Section 38.2.1.2, Sigma-Delta ADC analog input multiplexing](#)
- [Section 38.2.1.3, Sigma-Delta ADC clock sources](#)
- [Section 38.2.1.4, Sigma-Delta ADC starting/triggering](#)
- [Section 38.2.1.5, Sigma-Delta ADC external modulator](#)
- [Section 38.2.1.6, Conversion result interrupt/DMA](#)
- [Section 38.2.1.9, Sigma-Delta ADC analog input channel selection](#)

For detailed module information, refer to the Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface chapter.

38.2.1.1 Sigma-Delta ADC integration diagram

[Figure 442](#) shows the block diagram of the Sigma-Delta ADC integration on SPC57EM80xx. Note in the diagram that any unused Sigma-Delta ADC input can be read by SARADC_B. This is true for the unused input in single-ended operation.

Figure 442. Sigma-Delta ADC integration diagram

38.2.1.2 Sigma-Delta ADC analog input multiplexing

The analog input multiplexing switches are contained within the Sigma-Delta ADCs. A single analog switch pad cell is used for the Sigma-Delta analog input pins in order to share the pin with SARADC_B. The connection to the Sigma-Delta ADC inputs is made to the pad pin through the analog switch pad cell, shown in [Figure 442](#), and is controlled as follows:

- SARADC_B analog inputs are switchable by the SIUL2_MSCRn[APC] bit.
- SDADC analog inputs have no SIUL2_MSCRn[APC] bit control, but are directly connected to the pad.

The mapping of analog input pins to the Sigma-Delta converters is given in [Table 495](#).

38.2.1.3 Sigma-Delta ADC clock sources

Each Sigma-Delta ADC digital interface on the SPC57EM80xx has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE_n_CLK. The module clock is sourced by the modulator clock (SD_CLK). The input clock for the Sigma-Delta modulator is the SD_CLK. [Figure 443](#) gives a block diagram of the required Sigma-Delta ADC clock architecture. See the clocking chapter, [Section 27.6.7, Sigma-Delta ADC clocking](#), for more detail on the clock sources.

The frequency range for the SD_CLK is 4–16 MHz. Both the analog and digital blocks of the ADC contain an internal clock mux for external modulator mode. The external modulator clock (EXT_CLK) can be input to the device, or generated from SD_CLK from the CGM. The pad input/output settings in the corresponding SIUL2 MSCR pad control registers determine the external modulator clock source to the ADC blocks. The EXT_CLK pins are multiplexed on multiple external pins on the device. Selection of the EXT_CLK pin to use for the external modulator clock for each ADC is done in the SIUL2 MSCR input multiplexing registers. Each Sigma-Delta ADC has three external pins to select from for an external modulator clock.

Figure 443. Sigma-Delta ADC clock diagram

38.2.1.3.1 Clock Skew

To avoid crosstalk issues, all Sigma-Delta ADCs run at the same clock frequency. Independent programmable oversampling rates are provided to support the varying bandwidths of interest on each ADC in the application. Therefore, all Sigma-Delta analog blocks are clocked from the output of a single divider of the peripheral clock at the chip level.

38.2.1.4 Sigma-Delta ADC starting/triggering

Each Sigma-Delta ADC on SPC57EM80xx supports starting the converter with a software write to an enable bit in a register in the digital interface.

38.2.1.4.1 Simultaneous start of multiple Sigma-Delta converters

A method to start multiple Sigma-Delta converters simultaneously by a single software write to a control register is available on the device. Simultaneously in this case means that all selected converters start sampling their inputs on the same SD_CLK clock edge.

The digital interface of the Sigma-Delta ADC contains the control register for simultaneous start of the ADCs. When the register is written to start multiple converters, an output from the digital interface is asserted. The hardware trigger input of each Sigma-Delta ADC is connected to this simultaneous start output. This way the user controls which ADCs are selected by enabling the hardware trigger of desired ADCs before writing to the starting simultaneous converters.

The connections for the simultaneous start of the converters is given in [Figure 444](#).

Figure 444. Sigma-Delta ADC simultaneous start connectivity

38.2.1.4.2 Sigma-Delta mux input advance and wraparound

The mux wraparound feature is enabled and controlled in the digital interface of the Sigma-Delta ADC. The advancing of the mux can be controlled in the interface by software or by external GTM channels. The mapping of GTM output channels to the mux advance input for each Sigma-Delta ADC for each device is given in the SIUL2 MSCR registers.

38.2.1.5 Sigma-Delta ADC external modulator

38.2.1.5.1 External modulators

The Sigma-Delta ADC supports an interface to external Sigma-Delta modulators. In this mode, the Sigma-Delta ADC internal modulator is disabled, and a serial bit stream from an external modulator is clocked into the back-end digital filters of the on-chip Sigma-Delta ADC. Currently, the AMC1203 external modulator is supported by the Sigma-Delta ADC. It is possible that other external 2nd order modulators with clock rates less than 10 MHz and a compatible electrical interface (see SPC57EM80xx Data Sheet) could be supported.

The external modulator interface for each Sigma-Delta ADC on SPC57EM80xx is shown in [Figure 445](#).

Figure 445. Sigma-Delta ADC external modulator interface

38.2.1.5.2 External modulator clock/data inputs

Two external pins are required for each Sigma-Delta ADC to support an external modulator, an input data pin EXT_DATA (bitstream data), and an input/output clock pin EXT_CLK (bitstream clock). When the external modulator is used, the clock and data inputs to the Sigma-Delta ADC digital filters come from the EXT_CLK and EXT_DATA pins, instead of the internal modulator as shown in [Figure 453](#). External modulator operation is enabled in the ADC digital interface registers. The internal modulator is disabled. The EXT_CLK and

EXT_DATA inputs are multiplexed on port input pins. For each Sigma-Delta ADC, there are three sets of EXT_CLK/EXT_DATA pins, and selection of those pins for each ADC is done in the SIUL2 MSCR registers.

38.2.1.5.3 External modulator clock output

SPC57EM80xx provides an option for an output clock from the device to the external modulator. When providing an output clock, the SD_CLK from the CGM is connected to the EXT_CLK output pin. Both the input and output buffer of the EXT_CLK pin must be enabled in the corresponding SIUL2 MSCR register, in order for both the external modulator and internal filters to be clocked from the SD_CLK. This is shown in [Figure 445](#).

38.2.1.6 Conversion result interrupt/DMA

A DMA or interrupt can be generated for each conversion for each ADC. The Sigma-Delta ADC has an 8-deep result FIFO.

The Sigma-Delta ADC digital interface has an input signal that is used to disable interrupt and DMA requests for conversion results. The input signal is connected to outputs from the GTM timer block. The digital interface has a register bit for enabling and disabling the interrupt/DMA gating feature.

When the signal from the GTM is asserted, no interrupt or DMA request is generated for any conversion results. The polarity of the gating signal is such that when the signal is high, interrupt and DMA requests are passed. When the gating signal is low, interrupt and DMA requests are blocked.

The gating signal for each ADC is driven by several GTM channels. See [Chapter 16: System Integration Unit Lite2 \(SIUL2\)](#) for the specific mapping of GTM channels to Sigma-Delta interrupt/DMA gating signals.

38.2.1.7 Conversion Limit Watchdog Output to GTM

Each Sigma-Delta ADC provides an optional conversion limit check for upper and lower bounds. The enable bit and the two 16-bit limit registers for the feature are included in the SDADC wrapper. If a conversion result exceeds one of the limits, a flag bit is asserted in a status register in the SDADC wrapper. The flag bit is output to the GTM for each SDADC. The mapping of conversion limit watchdog outputs to GTM channels is defined in the SIUL2 MSCR registers.

38.2.1.8 SDADC_MCR[TRIGSEL] definitions

For this chip, the following input triggers apply:

TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware-triggered conversions. 0000 SDADC_0 0001 SDADC_1 0010 SDADC_2 0011 SDADC_3 0100 SDADC_4 0101 SDADC_5 0110 – 1110 Reserved 1111 MUX_ADV <i>Note: Selecting the input trigger source to be from the output trigger of the same SDADC is not prohibited by hardware, but is not supported, and will result in the SDADC never responding to the input trigger.</i>
---------	---

38.2.1.9 Sigma-Delta ADC analog input channel selection

For the Sigma-Delta mux inputs AN[x], the positive and negative input terminals are selected in the Sigma-Delta ADC digital interface Channel Selection Register (CSR).

This section shows analog channel selections for each combination of Module Configuration Register (MCR) field values MCR_MODE and MCR_VCOMSEL. The following table provides a quick reference key to the MCR fields used in the SD ADC analog input selection tables that follow it.

Table 496. Register fields for SD ADC analog input channel selection

Field	Description
MCR_VCOMSEL	Common Voltage Bias Selection This bit selects the common voltage bias for the negative input terminal of SDADC during single-ended mode (MODE=1). 0 Negative input terminal is biased with VREFN. 1 Negative input terminal is biased with VREFP/2 (half scale bias).
MCR_MODE	Mode selection 0 Differential input mode is selected. 1 Single-ended input mode is selected.
CSR_ANCHSEL	Analog Channel Selection Based on single-ended or differential mode of operation (MODE bit of MCR), common mode voltage selection (VCOMSEL bit of MCR), this bit-field defines the connectivity of analog inputs to either positive or negative polarity terminals of Sigma-Delta ADC, as shown in the following tables: – Table 497 for SDADC_0 – Table 498 for SDADC_1 – Table 499 for SDADC_2 – Table 500 for SDADC_3 – Table 501 for SDADC_4 – Table 502 for SDADC_5

38.2.2 Successive Approximation Register Analog-to-Digital Converter (SARADC)

There are eight independent SARADC_s on SPC57EM80xx. Refer to [Figure 441](#) for the ADC sub-system block diagram.

The following sections describe configuration details:

- [Section 38.2.2.1, SAR ADC integration diagram](#)
- [Section 38.2.2.2, SAR ADC analog input pin multiplexing](#)
- [Section 38.2.2.3, SAR ADC clock sources](#)
- [Section 38.2.2.4, SAR ADC triggering](#)
- [Section 38.2.2.5, SAR ADC alternate reference](#)
- [Section 38.2.2.6, SAR absolute voltage reference](#)
- [Section 38.2.2.7, SAR ADC diagnostic](#)
- [Section 38.2.2.8, SARADC channel assignment](#)
- [Section 38.2.2.9, SAR ADC register definitions](#)

For detailed module information, refer to the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

38.2.2.1 SAR ADC integration diagram

[Figure 446](#) shows the block diagram of the integration of the eight SAR ADCs on SPC57EM80xx.

SARADC_B implements a bias generator converting the VDD_HV_ADR_S, 1/3 VDD_HV_ADR_S, 2/3 VDD_HV_ADR_S, and VSS_HV_ADR_S reference points through the internal 20 kΩ source impedance. See the SARADC block diagram in the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

Figure 446. SAR ADC integration diagram

38.2.2.2 SAR ADC analog input pin multiplexing

All analog input pins routed to SARADC_B and another fast SAR ADC are multiplexed with a dual analog input switch pad cell. Analog input pins that only connect to SARADC_B use a single analog switch pad cell.

Note: Simultaneous sampling of two ADCs on same analog input is not allowed.

A second level of multiplexing is required for SARADC_B to reduce the parasitic capacitance on the analog input due to the 60:1 input mux. The second level muxing is done in an SoC level IP block so that it can be optimally placed for routing. The analog switches in the second level mux block are controlled by the SAR ADC digital interface block.

The mapping of analog input pins to the SAR converters is given in [Table 495](#).

38.2.2.3 SAR ADC clock sources

Each SAR ADC digital interface on SPC57EM80xx has a register clock input, which is separate from the module clock input. The register interface is clocked by the PBRIDGE $_n$ _CLK. The module clock is sourced by the ADC clock (SAR_CLK). See [Section 27.2, Clock generation](#) for more detail on the clock sources.

The input clock for the SAR ADC analog blocks is clocked by the SAR_CLK. [Figure 447](#) shows a block diagram of the SAR ADC clock architecture. The maximum frequency for the clock input to the converter is 14.6 MHz.

To avoid crosstalk issues, all SAR ADCs run at the same clock frequency. The SAR digital interface is clocked from the PBRIDGE $_n$ _CLK clock. All SAR analog blocks are clocked from the output of a single divider of the SAR_CLK at the device level.

Figure 447. SAR ADC clock diagram

38.2.2.4 SAR ADC triggering

Each SAR ADC has 16 independent trigger inputs for starting conversion on an analog input. Selection from the 16 trigger inputs is done inside the SAR ADC digital wrapper. Each SAR ADC on the device has an independent set of trigger inputs, but the same sources are used for each SAR ADC, so only one trigger input is required for each SAR ADC.

The trigger sources for each SAR ADC on the device are either external input pins or GTM channels. Each external input can selectively trigger any of the SAR ADCs on the device. The synchronization to the PBRIDGE clock and digital filtering of the external input pin triggers is done in the system integration logic.

Each trigger input supports software selectable options for rising edge, falling edge, rising and falling edge, or level-based trigger assertion. The trigger selection for each SAR ADC and edge/level selection is located in the SIUL2. The SPC57EM80xx SoC diagram for the SAR ADC trigger inputs is given in [Figure 448](#).

Figure 448. SARADC input trigger diagram

Trigger source selection for each SAR ADC is given in the SIUL2 chapter of this document.

38.2.2.5 SAR ADC alternate reference

The SAR ADCs support connection to more than one conversion reference. The alternate references are muxed with analog input pins on SPC57EM80xx. The analog input pins used as alternate references to the respective SAR ADCs are given in [Table 503](#).

Table 503. SARADC alternate references

SARADC	Alternate reference pin
SARADC_B	AN[8]
SARADC_2	AN[16]

To meet safety requirements, the reference for specific SAR analog inputs cannot be changed. For SPC57EM80xx, these are SARADC_B channels 4–7 and 35, and all other SAR analog inputs. For these SAR ADC instances that do not enable an alternate reference, ICDRn[REFSEL] is a read-only bit. There is no option to connect these pins as analog references for the device for safety considerations.

Alternate reference selection is enabled only for the following channels, for which ICDRn[REFSEL] is read-write bit:

- SARADC_B channels (0–3, 8–34, 36–95): See [Table 4, Section 38.2.2.9, SAR ADC register definitions](#).
- All SAR2 channels (16–19, 22–23): See [Table 9, Section 38.2.2.9, SAR ADC register definitions](#).

38.2.2.6 SAR absolute voltage reference

SPC57EM80xx provides an internal, absolute voltage reference that can be read by SARADC_B. The ADC conversion channel number for the absolute reference, ADC Bandgap Reference, is given in [Table 505](#).

38.2.2.7 SAR ADC diagnostic

38.2.2.7.1 Self Test features

Following are the Self Test features:

- The ADCBIAS provides four different voltage levels defined as GND, $V_{ref}/3$, $2*V_{ref}/3$ and V_{ref} . The self test internal reference voltage precision is provided in the SARn ADC electrical specification table of the device datasheet.
- The impedance requirement has been satisfied putting a physical poly resistor $R_{out} = 20\text{ k}\Omega$ typical characterized by a process and temperature variation of $\pm 30\%$.
- The impedance of the switches that are connecting the different references to the ADC input has not been considered in the impedance calculation.
- The impedance of the switches from the reference generation to the ADC input has been matched with the one of the switches that are connecting the device pin to the ADC input.
- The sampling time of SARADC_B needs to be extended to 2.2 ms due to long settling time induced by the high impedance of the source (20 k Ω).
- The SAR ADC Digital Interface provides the necessary control to select the required switches S1–S7 (shown in [Figure 449 \(Self Test implementation\)](#)) to perform the Self Test.

Figure 449. Self Test implementation

38.2.2.7.2 Internal reference

The SARB ADC provides the ability to sample and convert four internal voltages through a 20 kΩ source impedance. These voltages are as follows:

- $V_{DD_HV_ADR_S}$
- $\frac{1}{3} V_{DD_HV_ADR_S}$
- $\frac{2}{3} V_{DD_HV_ADR_S}$
- $V_{SS_HV_ADR_S}$

Conversion of an internal reference voltage works the same as that for a normal conversion, with the exception of the conversion time. Due to the 20 kΩ source impedance, the sampling time is much higher than the normal time.

Enabling the sampling and selection of an internal reference is independent of input channel selection for SARADC_B.

38.2.2.7.3 Analog input pin programmable pullup/pulldown

An open or short circuit condition is detectable within the device for analog input pins. There is a programmable pullup/pulldown pad cell at the input pad. This allows for application testing of the mux input logic. The analog input pin diagram with the pullup/pulldown is shown in [Figure 450](#). The pullup/pulldown is included inside the analog input pad cell. The pullup/pulldown is also included in the single switch analog input pad cell.

Control of the pullup/pulldown is independently done in the SIUL2 MSCR registers for each analog input pin.

Only the analog input pins specified in [Table 495](#) have the pullup/pulldown feature.

Figure 450. Analog input pin pullup/pulldown pad cell

38.2.2.7.4 Analog input pin switch to $V_{SS_HV_ADV}$

Two analog input pins on SPC57EM80xx have a programmable switch to $V_{SS_HV_ADV}$ to discharge the input. This switch is implemented on analog input pins AN7 and AN35 for SPC57EM80xx. The analog input diagram for AN35 is given in [Figure 451](#). The default state of the switch for both inputs is OFF.

Figure 451. Analog input AN35 — discharge switch to AVSS

The ground switches for AN7/AN35 are controlled independently from the input switch to the ADC. The ground switch for AN7/AN35 is controlled in input multiplexing MSCR registers (MSCR[WPDE]) in the SIUL2. The MSCR register provides selection between open or closed switch, with open being the default state.

The ground switches can be used to periodically discharge the associated channels.

38.2.2.8 SARADC channel assignment

The input multiplexer channel assignments for the SARADCs is provided in [Table 504](#).

38.2.2.8.1 Internal voltage monitor channel assignments

Each internal voltage monitor has a unique channel assignment, and is treated by software like any other A/D conversion. Access to the internal monitor channels is required for SARADC_B only. The internal voltage monitor channel assignments for SARADC_B are given in [Table 505](#).

Table 504. SAR analog input channel assignment

Analog input pin	SARADC_B input channel	Fast SAR	Fast SAR channel	Description

38.2.2.8.2 SARADC_B interface to PMC

The connection of the PMC to SARADC_B ADC is shown in [Figure 452](#). SARADC_B ADC channel 110 connects to the PMC. The PMC contains an analog mux that passes internal voltage nodes in addition to those given in [Table 505](#). The PMC mux is programmed in a register in the PMC digital interface. To convert an internal PMC voltage, the user programs the PMC analog mux selection, and then programs SARADC_B to convert PMC channel 110. See the Power Management chapter of this document for more info on additional internal voltages that can be read by the SARADC_B ADC.

Figure 452. SARADC_B ADC read of internal PMC voltages

38.2.2.9 SAR ADC register definitions

Each of the following sections shows register definitions for one SAR ADC instance:

- [Section 38.2.2.9.1, SARADC_B register definitions](#)
- [Section 38.2.2.9.2, SARADC_0 register definitions](#)
- [Section 38.2.2.9.3, SARADC_1 register definitions](#)
- [Section 38.2.2.9.4, SARADC_2 register definitions](#)
- [Section 38.2.2.9.5, SARADC_3 register definitions](#)
- [Section 38.2.2.9.6, SARADC_4 register definitions](#)
- [Section 38.2.2.9.7, SARADC_6 register definitions](#)
- [Section 38.2.2.9.8, SARADC_7 register definitions](#)

The following tables provide a key for the register definition tables. Test channels and external channels are only used for SARADC_B.

39 Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface

39.1 Introduction

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides accurate conversion data for a wide range of applications.

39.2 Overview

[Figure 453](#) depicts the block diagram of an SDADC and its digital control block. The SDADC digital interface block provides all control information for operating mode selection (single-ended or differential), analog input gain, decimation rate, high-pass filter enable, etc. It also generates the bias controls for common mode voltage selection, to bias the positive and negative terminals to different voltage levels (for example, half scale bias, reference ground, reference supply) for diagnostics. It generates the analog multiplexer control signals for the selected channels. It also provides external modulator support and keeps the internal modulator in low consumption mode. To assist synchronous operation across multiple ADC blocks, hardware trigger support is implemented to start data conversion.

Figure 453. SDADC block diagram

39.3 Features

- 16-bit data resolution output
- Single-ended input or differential input mode of operation
- Programmable wraparound mechanism for both modes of operation
 - Configurable trigger sources: hardware or software
 - Configurable initial entry and wraparound values for the loop
- Configurable biasing for negative input terminal in single-ended mode
- Gain and offset calibration support using fixed bias for input terminals
- Programmable decimation rate
- Programmable gain for analog inputs
- Optional external modulator support
- Optional high-pass filter for pure AC application
- Hardware trigger support for synchronous operation of multiple SDADC blocks
- Trigger event output generation by software
- Programmable FIFO structure for storing 16-bit converted data
- Interrupt/DMA request generation based on various conditions:
 - Data buffer at or above threshold
 - Data buffer overrun
 - WDG crossover event
- Programmable threshold range WDG support
- Low consumption mode
- Optional conversion process halt mechanism on SoC debug request

39.4 Modes of operation

This section describes the different operation modes of the SDADC. When exiting reset, the mode of operation is determined by the Module Configuration Register (MCR).

39.4.1 Differential input mode

This mode is entered by negating the MCR[MODE] bit. In this mode, a pair of analog inputs are connected to positive and negative terminals of ADC modulator. In order to support gain and offset calibration for diagnostics, it is possible in this mode to select fixed bias voltages to both input terminals.

39.4.2 Single-ended input mode

This mode is entered by asserting the MCR[MODE] bit. In this mode, the negative input terminal is biased with a fixed voltage based on selection information in MCR, and the other analog input is connected to the selected external analog channel.

39.4.3 External modulator mode

This mode is entered by asserting the MCR[EMSEL] bit. In this mode, the data stream and clock outputs from the external modulator available on EMDATA/EMCLK input pins are routed directly to the SDADC block. The internal modulator is bypassed in this mode. Only

the digital filters of the SDADC will be used for result calculation. The source for the external modulator clock can be the internal on-chip clock source or the direct clock output coming from the external modulator. The external pin function control for these pins must be configured in the integration logic on a device, and is not included in the SDADC digital interface.

39.5 External signal description

[Table 519](#) shows the list of signals driven by external pins. At the chip integration level, some of the digital and analog signals might share pins or may not be available external to the chip.

Table 519. Signal properties

Name	Port	Function	I/O	Reset	Pull-up
AN[0:7]	SoC-specific	Single-ended analog inputs or Differential pairs of analog inputs	I	—	—
EMDATA	SoC-specific	External modulator data input	I	0	—
EMCLK	SoC-specific	External modulator clock input	I	0	—
VREFP	SoC-specific	Voltage reference for SDADC	I	—	—
VREFN	SoC-specific	Ground reference for SDADC	I	—	—
AVDD	SoC-specific	Analog voltage supply for SDADC	I	—	—
AVSS	SoC-specific	Analog ground supply for SDADC	I	—	—
DVDD	SoC-specific	Digital voltage supply for SDADC	I	—	—
DVSS	SoC-specific	Digital ground supply for SDADC	I	—	—

39.5.1 Detailed signal descriptions

[Table 520](#) provides a detailed description of the external signals.

Table 520. Detailed signal descriptions

Signal	I/O	Description
AN[0:7]	I	Each analog input can be used as a single-ended analog input or one of a differential pair of analog inputs which is connected to either positive or negative terminals of the SDADC, depending on the mode of operation and polarity selection.
		State meaning Analog input
		Timing Can be sampled at any time by the ADC.
EMDATA	I	Data stream input provided by external modulator.
		State meaning Asserted—Data input is 1 Negated—Data input is 0
		Timing Assertion—May occur at any time, but data stream is valid only when external modulator is selected by MCR[MODSEL] = 1. Negation—Ignored when external modulator is not selected.

Table 520. Detailed signal descriptions (continued)

Signal	I/O	Description
EMCLK	I	Clock input provided by external modulator.
		State meaning Asserted—clock high level Negated—clock low level
		Timing Assertion—May occur at any time, but clock is valid only when external modulator is selected by MCR[MODSEL] = 1. Negation—Ignored when external modulator is not selected.

39.6 Memory map and register descriptions

39.6.1 Memory map

This section provides the memory map for the SDADC block.

Table 521. SDADC Digital interface memory map

Offset or address	Register	Register classification ⁽¹⁾	Location
0x0000	SDADC_MCR – Module Configuration Register	Saf-Relv	on page 1252
0x0004	SDADC_CSR – Channel Selection Register	Saf-Relv	on page 1256
0x0008	SDADC_RKR – Reset Key Register	No-Saf	on page 1258
0x000C	SDADC_SFR – Status Flag Register	No-Saf	on page 1259
0x0010	SDADC_RSER – Request Select and Enable Register	Saf-Relv	on page 1260
0x0014	SDADC_OSDR – Output Settling Delay Register	Saf-Relv	on page 1262
0x0018	SDADC_FCR – FIFO Control Register	Saf-Relv	on page 1263
0x001C	SDADC_STKR – Software Trigger Key Register	No-Saf	on page 1264
0x0020	SDADC_CDR – Converted Data Register	No-Saf	on page 1265

1. Saf-Relv = Safety Relevant, No-Saf = Not Safety Relevant.

39.6.2 Register descriptions

This section provides the block's register bit descriptions in address order.

39.6.2.1 Module Configuration Register (MCR)

The Module Configuration register (MCR) consists of different control bits to select the operating modes and various configuration settings which define the behavior of the SDADC block.

Figure 454. Module Configuration Register (MCR)

Offset 0x0000												Access: User Read/Write

Table 522. MCR field descriptions

Field	Description
0–2	Reserved
3–7 PDR	Programmable Decimation Rate This field selects the over-sampling ratio to be applied to support different passbands with a fixed input sampling clock. The output data rate f_d is equal to $f_s / (2 \times \text{OSR})$, where f_s is the input sampling clock frequency. When external modulator is selected, the output data rate is independent of this field and is fixed to $f_s / 256$. 00000 OSR = 24 00001 OSR = 28 00010 OSR = 32 00011 OSR = 36 00100 OSR = 40 00101 OSR = 44 00110 OSR = 48 00111 OSR = 56 01000 OSR = 64 01001 OSR = 72 01010 OSR = 75 01011 OSR = 80 01100 OSR = 88 01101 OSR = 96 01110 OSR = 112 01111 OSR = 128 10000 OSR = 144 10001 OSR = 160 10010 OSR = 176 10011 OSR = 192 10100 OSR = 224 10101 OSR = 256 10110 Reserved 11111 Reserved
8	Reserved
9–11 PGAN	Programmable Gain This field selects the gain to be applied to the analog input stage of the SDADC. The effective analog input becomes the input voltage level multiplied by the gain factor. 000 Gain = 1 001 Gain = 2 010 Gain = 4 011 Gain = 8 100 Reserved 101 Reserved 110 Reserved 111 Gain = 16
12	Reserved
13	Reserved
14 EMSEL	External Modulator Selection 0 External modulator data and clock inputs are ignored 1 External modulator data stream and clock inputs are provided to SDADC

Table 522. MCR field descriptions (continued)

Field	Description
15 HPFEN	High Pass Filter Enable 0 High-pass (DC removal) filter is disabled 1 High-pass (DC removal) filter is enabled
16 WDGEN	Watchdog Enable This bit enables the WDG monitor. 0 WDG disabled 1 WDG is enabled
17–18 TRIGEDSEL	Trigger Edge Selection 00 Falling edge of trigger input is selected 01 Rising edge of trigger input is selected 1x Both edges of trigger input are selected
19 TRIGEN	Trigger Enable This field enables the hardware trigger input to initiate a fresh conversion. Upon receiving a trigger event, SDADC reset input is asserted and deasserted synchronously with respect to the peripheral clock. The reset pulse width is fixed to four peripheral clock cycles. The trigger event is ignored if the SDADC internal modulator is not enabled (MCR[EN] = 0) or the external modulator is selected (MCR[EMSEL] = 1). 0 Trigger input is disabled 1 Trigger input is enabled
20–23 TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware-triggered conversions. 0000 Input trigger 0 is selected 0001 Input trigger 1 is selected ... 1111 Input trigger 15 is selected
24 FRZ	Freeze This field enables stopping the SDADC conversions at the end of the current channel conversion when the SoC enters debug mode. When the SoC enters debug mode, further conversions by the SDADC analog block will be stopped, and converted data output from the SDADC analog block are ignored. The ongoing channel conversion will be completed and the converted data is stored. When the SoC exits debug mode, SDADC resumes the job that was left before halting the conversions. 0 Conversions are not stopped 1 Conversions are stopped
25–26	Reserved
27 VCOMSEL	Common Voltage Bias Selection This field selects the common voltage bias for the negative input terminal of the SDADC during single-ended mode (MODE = 1). 0 Negative input terminal is biased with VREFN 1 Negative input terminal is biased with VREFP/2 (half-scale bias)
28 WRMODE	Wrap-Around Mode This bit selects the wraparound mechanism for conversion of programmed sequence of channels. 0 Wraparound mechanism disabled (in this case the default software control mechanism will be enabled) 1 Wraparound mechanism enabled

Table 522. MCR field descriptions (continued)

Field	Description
29 GECEN	Accurate Gain Error Mode Enable This bit selects the accurate gain error mode, and must be set during gain error calibration as well as during conversions requiring accurate gain error mode. It can be kept '0' if gain error calibration mode is not needed. 0 Gain error calibration mode disabled 1 Gain error calibration mode enabled
30 MODE	Mode selection 0 Differential input mode selected 1 Single-ended input mode selected
31 EN	Enable for SDADC block 0 SDADC internal modulator placed in low consumption mode 1 SDADC internal modulator enabled

39.6.2.2 Channel Selection Register (CSR)

The Channel Selection Register (CSR) selects analog inputs AN[0:7] to be connected to positive and negative terminals of the SDADC and controls the biasing of analog inputs to half-scale bias through 100 kΩ resistance.

Figure 455. Channel Selection Register (CSR)

Offset 0x0004												Access: User Read/Write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 523. CSR field descriptions

Field	Description
0–7	Reserved
8–15 BIASEN[7:0]	Bias enable If BIASEN[i] = 1, analog input AN[i] (could be single-ended input or differential analog input) is connected to half-scale bias through a 100 KΩ resistor.
16–20	Reserved

Table 523. CSR field descriptions (continued)

Field	Description
21–23 ANCHSEL_WRAP	Analog Channel Selection Wraparound Value (ANCHSEL_WRAP) When in wraparound mode, this field indicates the maximum value of the wraparound counter, after which it will wrap around back to initial value 000. This value should be programmed before enabling wraparound mechanism (MCR[WRMODE] = 1).
24–28	Reserved
29–31 ANCHSEL	Analog Channel Selection(ANCHSEL) Based on single-ended or differential mode of operation (MCR[MODE]), common mode voltage selection (MCR[VCOMSEL]), this field defines the connectivity of analog inputs to either positive or negative polarity terminals of the SDADC according to Table 524 . Wraparound Mode: – This field also indicates the initial entry value for the first loop of the wraparound sequence from where the wraparound counter will start incrementing when wraparound mode is entered (when wraparound mechanism enabled (MCR[WRMODE] = 1)). – If this field is written any time during wraparound mode (when MCR[WRMODE] = 1), the present value of the wraparound counter will be updated with the value of ANCHSEL — the next trigger will act on the updated channel, and the next increment will be on the updated channel. Here, the value of ANCHSEL chosen should be < ANCHSEL_WRAP; otherwise it will be ignored by hardware. – Wraparound will always be from initial counter value 000.

Field	Description
0–15	Reserved
16–31 RESET_KEY[15:0]	Reset Key This field, when written with 0x5AF0, is used to generate the reset for the SDADC block and to reload the internal counter with the start value programmed in OSDR. Any write access to this register which is different from the predefined key is ignored. Read access will always return the inverted key.

39.6.2.4 Status Flag Register (SFR)

The Status Flag Register (SFR) contains status and flag bits. These bits are set by hardware and reflect the status of the SDADC and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing '1' to those bits. Writing a '0' to a flag has no effect.

Figure 457. Status Flag Register (SFR)

Table 526. SFR field descriptions

Field	Description
0–12	Reserved
13–15 ANCHSEL_CNT	Analog Channel Selection Counter(ANCHSEL_CNT) This field reflects the current value of the internal Analog Channel Selection Counter. It indicates the present number of the channel selected through the analog multiplexer.
16–22	Reserved
23 DFF	Data FIFO Empty Flag This field is asserted when there is no dataword in the FIFO. 0 Data FIFO is not empty 1 Data FIFO is empty
24–26	Reserved
27 WTHH	Watchdog Upper Threshold Cross Over Event This field is set when Converted Data crosses Upper Threshold of WDG. It can be cleared by software writing '1' to clear. 0 Watchdog Upper Threshold Cross Over Event did not occur 1 Watchdog Upper Threshold Cross Over Event occurred
28 WTHL	Watchdog Lower Threshold Cross Over Event This field is set when Converted Data crosses Lower Threshold of WDG. It can be cleared by software writing '1' to clear. 0 Watchdog Lower Threshold Cross Over Event did not occur 1 Watchdog Lower Threshold Cross Over Event occurred

Table 526. SFR field descriptions (continued)

Field	Description
29 CDVF	Converted Data Valid Flag This field gives the actual status of data coming from the SDADC block. The converted data is not valid or becomes corrupted whenever there is a change in configuration settings determined by MCR, channel selection programmed in CSR. Any write access to the registers MCR and CSR will reset this flag. This flag is set automatically after generating SDADC reset and internal timer counts OSD cycles of output clock f_d. 0 Data output from SDADC is not valid 1 Data output from SDADC is valid
30 DFORF	Data FIFO Overrun Flag This field indicates that software or DMA failed to prevent FIFO from overflowing with converted datawords. Software can clear this bit by writing '1' to it after reading the FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords will not be received into FIFO even if sufficient room exists. 0 No overrun has occurred since the last time the flag was cleared 1 Overrun has occurred or the DFORF has not been cleared since the last overrun occurred
31 DFFF	Data FIFO Full Flag This bit is set when the number of converted datawords in the FIFO is equal to or more than the number indicated by FCR[FTHLD]. Software can clear this bit by writing '1' to it. This bit is also cleared by an acknowledgement from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, datawords will continue to be received until an overrun condition occurs. Datawords will not be received if the converted data is not valid (CDVF = 0). 0 The number of datawords in FIFO is less than the number indicated by FCR[FTHLD] 1 The number of datawords in FIFO is equal to or greater than the number indicated by FCR[FTHLD] at some point in time since this flag was last cleared

39.6.2.5 Request Select and Enable Register (RSER)

The Request Select and Enable Register (RSER) serves two purposes:

- Enables the flag bits in SFR to generate DMA requests or interrupt requests.
- Selects the type of request to generate.

Refer to the field descriptions for the type of requests that are supported.

Figure 458. Request Select and Enable Register (RSER)

Table 527. RSER field descriptions

Field	Description
0–13	Reserved
14 WTHDIRS	WDG Threshold Cross Over Event DMA/Interrupt Request Select When SFR[WTHH/WTHL] and RSER[WTHDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
15 DFFDIRS	Data FIFO Full DMA/Interrupt Request Select When the SFR[DFFF] and SFR[DFFDIRE] fields are set, this field selects between generating a DMA request or an interrupt request. 0 Interrupt request is selected 1 DMA request is selected
16 GDIGE	Global DMA/Interrupt Gating Enable This field determines whether all module interrupts and DMA requests need to be gated by an external gating signal or not. 0 No impact of external gating signal on module DMA/interrupt requests 1 All module DMA/interrupt requests are qualified only when external gating signal is asserted
17–27	Reserved
28 WTHDIRE	WDG Threshold Cross Over Event DMA/Interrupt Request Enable This field enables the SFR[WTHH/WTHL] field to generate a request. The WTHDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt/DMA request is disabled on WDG Threshold Cross Over Event 1 Interrupt/DMA request is enabled on WDG Threshold Cross Over Event

Table 527. RSER field descriptions (continued)

Field	Description
29 CDVEE	Conversion Data Valid Event Enable This field enables the SFR[CDVF] field to generate a hardware event to be used at SoC level. Once enabled, the event output will remain asserted as long as valid data conversions are ongoing. 0 Event output disabled 1 Event output assertion/deassertion based on the SFR[CDVF] field
30 DFORIE	Data FIFO Overrun Interrupt Enable This bit enables the SFR[DFORF] field to generate an interrupt request. The final interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt request is disabled when data FIFO overrun condition occurs 1 Interrupt request is enabled when data FIFO overrun condition occurs
31 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable This field enables the SFR[DFFF] field to generate a request. The DFFDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. 0 Interrupt/DMA request is disabled when data FIFO full condition occurs 1 Interrupt/DMA request is enabled when data FIFO full condition occurs

39.6.2.6 Output Settling Delay Register (OSDR)

The Output Settling Delay Register (OSDR) provides a delay value to qualify the converted output data coming from the SDADC.

Figure 459. Output Settling Delay Register (OSDR)

Offset 0x0014								Access: User Read/Write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 528. OSDR field descriptions

Field	Description
0–23	Reserved
24–31 OSD[7:0]	Output Settling Delay This field defines the delay to qualify the conversion data stored in CDR. Whenever the SDADC block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value. The counter counts down with output clock f_d until it reaches zero, and then it generates a flag which qualifies the converted data. The output clock f_d is equal to $f_s / (2 \times \text{OSR})$, where f_s is the input sampling clock frequency. When external modulator is selected, the output clock is fixed to $f_s / 256$.

39.6.2.7 FIFO Control Register (FCR)

The FIFO Control Register (FCR) provides the ability to turn on and off the FIFO functionality, and to select the size of FIFO depth. This register also provides the ability to set the programmable threshold for notification of dataword removal from the FIFO. This register may be read at any time, but should only be written when SDADC is disabled ($\text{MCR}[\text{EN}] = 0$).

Figure 460. FIFO Control Register (FCR)

Offset 0x0018												Access: User Read/Write

Table 532. WTHHLR field descriptions

Field	Description
0–15 THRH	WDG Upper Threshold Value This indicates the upper threshold for the converted data on any channel, above which threshold a crossover event would be flagged through SFR[WTHH].
16–31 THRL	WDG Lower Threshold Value This indicates the lower threshold for the converted data on any channel, below which threshold cross over event would be flagged through SFR[WTHL].

Note: A single WDG monitor will check for lower and upper threshold crossover events.

39.7 Functional description

The SDADC has four distinct available modes determined by fields in MCR.

- Differential input mode
- Single-ended input mode
- External modulator mode
- Low consumption mode

39.7.1 Differential input mode

After system reset exit, this is the default mode of operation if SDADC is enabled by asserting MCR[EN]. This mode is entered by negating MCR[MODE]. In differential input mode, a pair of analog inputs among AN[0:7] is connected to the input terminals of the SDADC modulator block. The module supports four differential pairs: AN[0,1], AN[2,3], AN[4,5], and AN[6,7].

The modulator block has two input terminals, positive (INP) and negative (INM). The selection of input pair depends on the ANCHSEL field of CSR. The connectivity of each analog input in a given differential pair, whether it is connected to positive or negative

terminal, is determined according to [Table 524](#).

The differential input mode can also be used to perform gain and offset calibration, where the input terminals are biased with fixed voltages coming from the bias block.

39.7.2 Single-ended input mode

Single-ended input mode is entered by asserting MCR[MODE]. In this mode, one of the analog inputs among AN[0:7] is selected by the ANCHSEL field of CSR, and is connected to the positive terminal. The negative input terminal is biased with a fixed internal voltage. There are two internal bias voltages available: reference ground (VREFN) and half-scale bias (VREFP/2). The selection of this common mode voltage is controlled by MCR[VCOMSEL].

39.7.3 External modulator mode

This mode is selected by asserting the MCR[EMSEL] field. When external modulator is selected, the internal modulator can be put in low consumption mode by deasserting the MCR[EN] field. In this mode, the data stream and clock outputs from the external modulator available on EMDATA/EMCLK input pins are multiplexed with internal modulator data output and input sampling clock (f_s). External modulator data must be synchronized with respect to the falling edge of EMCLK. In this mode, hardware trigger input is ignored even if it is enabled by asserting the MCR[TRIGEN] field. All other configuration settings (for example gain, decimation rate, filter, etc.) programmed in MCR have no effect on the conversion.

39.7.4 Low consumption mode

This is the default mode after exiting from reset. This mode is exited by asserting the MCR[EN] field to enable the SDADC block. When data conversion is not required, the SDADC internal modulator can be put in low consumption mode to reduce power consumption.

39.7.5 Analog input multiplexing and bias support

The complete selection and connectivity of analog inputs AN[0:7] is based on the ANCHSEL field of CSR and the MODE and VCOMSEL bits of MCR, according to [Table 524](#). Each analog input can be biased to half scale ($AVDD/2$) via on-chip 100 k Ω resistance. This allows simple AC coupling to the external analog inputs through a capacitor. This biasing is applicable irrespective of whether analog channel is selected through multiplexer or not.

39.7.6 Programmable gain and decimation rate

All analog inputs can be configured to have a selectable input gain as defined in the PGAN field description in MCR. This means the input signal is sampled and the result is amplified by the factor determined by PGAN before providing the same to modulator.

The SDADC module is provided with a fixed input sampling clock f_s . The input signal is grossly oversampled by the modulator in order to reduce quantization noise. To support different passbands with a fixed sampling clock, a programmable decimation rate is implemented. The process of decimation, to eliminate redundant data at the output while retaining the necessary information, is controlled by the field PDR in MCR.

39.7.7 High-pass filter support

For pure AC applications, it is useful to remove any DC component in the input signal. An optional high-pass filter is implemented which can be enabled by asserting the MCR[HPFEN] field. The -3 dB frequency of the filter is fixed (not programmable) and is available in the device data sheet. This high-pass filter is implemented in the decimation filter logic of the SDADC and is applicable only to internal modulator mode.

39.7.8 Data conversion

Software Control Mechanism: The SDADC block will be in continuous conversion mode as soon as it is enabled. The conversion data is not accurate enough for some time, depending on the latency and output settling time specifications. This is true even when there is any change in the configuration settings provided by MCR, change in the analog channel selection due to mux switching time. To account for these delays, an internal timer is implemented which counts down from a start value determined by the OSD field of OSDR. This timer is reloaded whenever the RESET_KEY of RKR is written with 0x5AF0, which is required to start SDADC conversion from a fresh state with a changed configuration. The timer is stalled on reaching count '0' and asserts the SFR[CDVF] field. Once this flag is asserted, converted data is loaded into data FIFO on every rising edge of the output clock (f_d).

Any write access to the MCR and CSR registers will deassert the CDVF flag bit to indicate that data coming from SDADC is not valid or corrupted. If the CDVF flag is reset, the flags DFFF and DFORF are blocked from becoming asserted, i.e. transitioning from inactive state to active state. If DFFF bit is already set, this means the data FIFO is already full before CDVF deassertion.

The DFF flag bit (which not conditioned by the interrupt or DMA selection) is provided outside which can be routed to timer module at SoC level. **Wraparound Control Mechanism:** Here a wrap-around logic shall include all analog channels of the input multiplexer from Ain("000") to Ain(CSR[ANCHSEL_WRAP]) in both Single ended and Differential ended mode in wraparound sequence triggered by Harare or software source:

- MCR[WRMODE] bit would enable or disable the wraparound mechanism. Clearing the WRMODE bit automatically switches FSM back to Software control mode.
- Every valid trigger advances the wraparound counter to next channel to be converted.
- **Wraparound Counter:** An internal wraparound counter which points to analog channel to be converted takes the initial entry value for the first loop of execution from CSR[ANCHSEL] while entering wraparound mode. From next loop onwards the counter wraparounds to default initial value "000". Maximum value of the counter (wraparound value) should be programmed in CSR[ANCHSEL_WRAP] before entering wraparound mode, definition of ANCHSEL and ANCHSEL_WRAP is provided in [Section Table 524., Analog input AN\[0:7\] selection](#).
- Upon entering or during wraparound mode user should take care to program ANCHSEL value < ANCHSEL_WRAP value, otherwise hardware would reject the new ANCHSEL value.
- Possible trigger sources:
 - SOURCE1(Software Bit): writing to STKR.ST_KEY at any time during the wraparound mode (irrespective of MCR[TRIGEN or TRIGSEL] setting) generates a trigger pulse, each such trigger initiates a fresh conversion and advances the wraparound counter by one. Note: Care should be taken while programming the

- TRIGEN/TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.
- SOURCE2(Hardware Trigger): Here external trigger output (for e.g., mux_advance of GTM) enabled by MCR[TRIGEN or TRIGEDSEL or TRIGSEL] before entering wraparound mode for selective or all SDADC instances provides trigger, each such valid trigger initiates a fresh conversion and advances the wraparound counter by one. One of the hw_trig_in ports can be used to connect the external trigger output.
 - Next channel number to be converted can be updated by software even in the middle of wraparound sequence execution, this can be done by rewriting CSR[ANCHSEL]. After CSR[ANCHSEL] is rewritten, the next trigger takes updated value (wraparound counter would increment from the updated value).
 - Current wraparound counter value can be read from SFR[ANCHSEL_CNT] bitfield.

39.7.9 Hardware triggering

Software Control Mechanism: SDADC conversion can be triggered by various hardware events coming from either external pins or internal timers. The field TRIGSEL of MCR selects which hardware event is to be used for triggering conversions. This trigger event, which is synchronous to the peripheral clock, is enabled by asserting MCR[TRIGEN]. As soon as a trigger event is detected, reset input of SDADC block is asserted synchronously for four cycles. This will ensure that SDADC starts from a fresh state when reacting to the input trigger event. The SDADC internal modulator must be enabled before enabling the trigger event — otherwise the trigger event will be ignored. A hardware trigger event is also ignored when external modulator is selected (MCR[EMSEL] = 1).

If the same trigger event is provided to multiple SDADC digital interface modules and the respective enable controls (TRIGEN bit MCR) are asserted, synchronous operation of multiple SDADC blocks can be achieved with output results being updated at the same time. Once the reset input is deasserted, the first valid conversion output is stored in data FIFO after a configurable delay determined by OSDR[OSD].

It is also possible to generate a software trigger event output by a write access of STKR with a predefined key. This event output can be used as a trigger to achieve synchronous software start of multiple SDADC blocks.

In case of a hardware trigger, the skew/jitter will be less than 100 ns. It will be more than one ADC clock cycle due to synchronization. In case of a software trigger, all SDADCs start synchronous sampling.

Wraparound Control Mechanism: In wraparound control mode, hardware and software triggers are equally valid. The hardware trigger source should be selected before enabling the wraparound mode.

39.7.10 Interrupt/DMA request support

The SDADC has one condition that generates interrupts only and another that generates interrupts or DMA request.

The DFFF field is asserted when the data FIFO full condition is detected, indicating that the number of converted datawords stored in data FIFO is equal to or greater than the value indicated by threshold determined by FCR[FTHLD]. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

The data FIFO overrun flag (DFORF) indicates the FIFO overflow condition. Further converted datawords cannot be received and data is lost. The interrupt request is generated only when RSER[DFORIE] is asserted.

Apart from above, a WDG threshold crossover event can also generate an interrupt or DMA request.

If RSER[GDIGE] is set, all module interrupt/DMA requests are qualified only when an external global gating signal is asserted.

39.7.11 Gain calibration support

To perform gain calibration, the following sequence needs to be applied.

1. Select differential mode of operation by writing MCR[MODE] to '0'.
2. Enable gain error calibration mode by writing MCR[GECEN] to '1'.
3. Configure the mux selection ANCHSEL field of CSR to '110'. This configuration will apply VREFP on positive terminal and VREFN on negative terminal.
4. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 0x00.
5. Disable the high-pass filter by deasserting MCR[HPFEN].
6. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
7. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 0b0111_1001_1001_1001, corresponding to full positive scale after attenuation inserted by the internal filter (1×0.95). The measurement should be repeated to reduce contribution of noise during calibration process. D_p is the average value of attenuated positive full scale given by $D_p = \text{AVERAGE}(\text{CDR}[\text{CDATA}])$.
8. Change the mux selection ANCHSEL field of CSR to '111'. This configuration will apply VREFN on positive terminal and VREFP on negative terminal.
9. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
10. Read the digital output (CDR[CDATA]) stored in FIFO after the output settling time. Expected output if there is no gain error is 0b1000_0110_0110_0110, corresponding to full negative scale after attenuation inserted by the internal filter (-1×0.95). The measurement should be repeated to reduce contribution of noise during calibration process. D_n is the average value of attenuated negative full scale given by $D_n = \text{AVERAGE}(\text{CDR}[\text{CDATA}])$.
11. The SDADC calibrated gain can be calculated as:

$$\text{Gain} = (D_p - D_n) / 2^{16}$$
12. The measured gain value can be used to nullify the gain errors in the digital output. For calibrated conversion, the data CDR[CDATA] provided by the SDADC should be normalized using the calculated gain: $\text{CDATA}_{\text{norm}}$ is given by $\text{CDATA}_{\text{norm}} = \text{CDR}[\text{CDATA}] / \text{Gain}$.

Note: The gain error calibration should only be done with gain equal to '1' (in other words, PGAN = 000). Nevertheless, the calculated gain can be applied to normalized data also for conversion with GAIN > 1.

Note: MCR[GECEN] = 1 ensures the accurate gain error mode is enabled. This bit should be set both during calibration process and after calibration, for application data conversion. Application data conversion must then be normalized using the measured gain.

Note: The higher the number of full-scale conversion (D_p , D_n) done, the higher the rejection of noise during the calibration. The number of conversion is dependent on application noise. It is recommended to run at least 16 conversions when calculating an average value.

39.7.12 Offset calibration support

To perform offset calibration, the following sequence must be applied.

1. Select differential mode of operation by writing MCR[MODE] to '0'.
2. Configure the mux selection ANCHSEL field of CSR to '100' or '101' as required.
 - a) CSR = '100' in case of data conversion after calibration in "single ended mode with negative input = $V_{SS_HV_ADR_D}$ "
 - b) CSR = '101' in case of data conversion after calibration in "differential mode" and "single ended mode with negative input = $(V_{DD_HV_ADR_D} - V_{SS_HV_ADR_D})/2$ "
3. Disable the bias on all input analog channels by writing ENBIAS field of CSR to 0x00.
4. Disable the high pass filter by deasserting MCR[HPFEN].
5. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
6. Read the digital output stored in FIFO after the output settling time.
7. The measured offset can be used to nullify the offset error in the digital output. Expected output is 0b00_0000_0000_0000. The SDADC offset can be calculated as:
 Offset = Expected Output – Actual Output

Note: The offset must be calculated for each PGAN field setting since it is expected to vary with gain configuration of SDADC.

39.8 Initialization information

To initialize the SDADC registers for data conversion, the following sequence is required.

1. Enable the SDADC by asserting MCR[EN].
2. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
3. Enable high-pass filter if required.
4. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
5. Configure OSD delay according to SDADC startup time or latency from reset exit.
6. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR. Otherwise, if data conversion need to be triggered by a hardware event, assert MCR[TRIGEN].
7. DFFF interrupt or DMA request will be generated after the data FIFO has reached threshold to indicate that data can be transferred.

The following sequence needs to be followed when external modulator mode of SDADC is selected for data conversions.

1. Disable the SDADC internal modulator by deasserting MCR[EN].
2. Configure MCR to select the external modulator mode.
3. Select the required external pins EMDATA/EMCLK in the system integration logic (SIUL) of the device.
4. Configure OSD delay according to external modulator startup time or latency from reset exit.
5. Generate a reset event by writing 0x5AF0 to RESET_KEY of RKR.
6. DFFF interrupt or DMA request will be generated after the data FIFO has reached threshold to indicate that data can be transferred.

40 Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface

40.1 Introduction

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for the application. It provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has its corresponding digital interface implemented at the SoC level.

40.2 Overview

The SARADC digital interface contains advanced features for normal or injected conversion modes of operation. The conversion can be triggered by software or hardware.

The digital interface can be configured to control up to 256 multiplexed analog input channels. There are three types of input channels:

- Internal channels, mapped to index ranging from 0 to 95
- Test channels, mapped to index ranging from 96 to 127
- External channels, mapped to index ranging from 128 to 255

Note: The number of input channels and their mapping varies depending on your device configuration. See the device-specific Analog-to-Digital Converters (ADC) Configuration section (analog input pin multiplexing and SAR ADC channel assignment) for a channel mapping table.

The mask registers present within the digital interface can be properly programmed to configure which channel has to be converted. External channel selection is provided through external decode signals and are available as alternate functions on GPIO. Each set of eight external channels can be mapped to any internal analog channel by static programming by software in specific registers.

Four conversion timing registers exist that allow configuration of different precharging and sampling durations, and it is possible to select one of the conversion timing registers for each channel. For each channel, it is possible to choose the voltage reference through software. Analog Watchdogs allow continuous hardware monitoring of analog input channels. The digital interface also provides for interrupt/DMA support for various conditions related to end of channel conversions.

Figure 464 shows the SARADC block diagram.

Note: SARB implements a bias generator converting the V_{ddm} , $1/3 V_{ddm}$, $2/3 V_{ddm}$, and V_{ssm} reference points through the internal 20 k Ω source impedance.

1. Test channels are mapped to internal analog channels via the SARADCB_TCCAPRx registers

Figure 464. SARADC block diagram

40.3 Feature description

40.3.1 Main features

- Selectable 10-bit or 12-bit data resolution output
- Up to 96 internal channels, 32 test channels, 128 external channels supported; variable number of analog channels of each type controlled by parameters
- 4 different conversion timing registers selectable for any channel
- Mapping of external channel to any internal channel through static programming by software
- Shorting of test channel with internal channel through static programming by software
- External decode signals (3 signals) for selection of external analog mux inputs
- Normal conversion with One Shot/Scan modes
- Injected conversion with One Shot mode
- Normal conversion with dedicated trigger input
- Injected conversion with dedicated trigger input
- 2 different abort features that allow to abort either a single channel conversion or chain conversion
- Reference selection for each channel
- Power Down Mode
- Dedicated data register for each channel, containing the following information:
 - 10-bit or 12-bit conversion result in one half-word
 - Status byte which provides some conversion information such as mode of operation (Normal, Injected), data valid, data overwritten status
 - Control byte for reference selection, conversion timing parameter selection
- Configurable number of analog watchdogs
 - Trigger outputs on watchdog threshold crossover events
- Interrupt/DMA support for the following conditions
 - End of conversion of single channel for both normal, injected conversions
 - End of conversion chain for both normal, injected conversions
 - Watchdog thresholds crossover

40.4 Functional description

Two main conversion types are available within the SARADC digital interface:

- Normal conversion
- Injected conversion

40.4.1 Normal channel conversion

This is the normal conversion that the user programs by configuring the normal conversion mask registers (ICNCMR0–2, TCNCMR, ECNCMR0–3). Each channel can be individually enabled by setting '1' in the corresponding field of these registers. Mask registers must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends (MSR[NSTART] bit is reset).

40.4.1.1 Start of normal conversion

The normal conversion can be started as follows:

- By software
 - The normal conversion chain starts when the MCR[NSTART] bit is set. It is recommended that the normal trigger enable MCR[NTRGEN] bit is reset during conversions started by software. Once normal conversion has started, any further write operation of MCR[NSTART] bit will have no effect during ongoing conversion, but the conversion will be enqueued after completion of current conversion in oneshot mode.
- By normal trigger
 - A normal trigger valid edge or level is detected to start the conversion. The normal trigger is enabled by setting the NTRGEN bit in MCR and two options are available. A programmed event (rising, falling or both edges depending on NEDGESEL bitfield of MCR) on the normal trigger input starts the normal conversion. Once normal conversion has started, any further valid trigger edge will be ignored during ongoing conversion. If the trigger mode is enabled (MCR[NTRGEN] bit is set), then software can only clear the MCR[NSTART] bit for terminating the conversion process. It is not possible to software to give any conversion request.

40.4.1.2 Normal conversion operating modes

Two operating modes are available for the normal conversion:

- One Shot Mode
- Scan Mode

To enter one of these modes, it is necessary to program the MCR[MODE] bit. The first phase of the conversion process involves sampling the analog channel and the next phase involves the conversion phase when the sampled analog value is converted to digital as shown in [Figure 465](#).

Figure 465. Normal conversion flow

In **One Shot Mode** (MODE = 0), a sequential conversion specified in the ICNCMR0–2, TCNCMR, ECNCMR0–3 mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored into the corresponding data register.

For Example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the *One Shot Mode*. MODE = 0 is set for One Shot mode. Conversion starts from the channel B followed by conversion of channels D-E. At the end of conversion of channel E the scanning of channels stops.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time MCR[NSTART] bit is reset if the conversion is started by software.

Once the normal conversion operation starts in oneshot mode and another software conversion request is made writing the MCR[NSTART] bit and before MSR[NSTART] is cleared, one additional conversion is initiated with the same channel mask register settings after the current conversion is finished, this is called **enqueuing**. Enqueuing can help in

removing the delay between two consecutive oneshot chains and uncertainty caused by metastability between MCR[NSTART] bit written at system clock and generation of start pulse on ADC clock before every chain execution.

In **Scan Mode** (MODE = 1), a sequential conversion of N channels specified in the ICNCMR0–2, TCNCMR, ECNCMR0–3 registers is continuously performed. As in the previous case, at the end of each conversion the digital result of the conversion is stored into the corresponding data register.

In this mode, the software can start conversion by writing '1' to MCR[NSTART] bit or a valid normal trigger edge is detected which also sets MCR[NSTART] bit. The MCR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One Shot Mode, the MCR[NSTART] bit is not reset. It can be reset by software when the user needs to stop scan mode. In that case, the current scan conversion is completed and MCR[NSTART] bit also is reset after the last conversion of the chain.

For Example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in the *Scan Mode*. MODE = 1 is set for Scan Mode. Conversion starts from the channel B followed by conversion of the channels D-E. At the end of conversion of channel E the scanning of channel B starts followed by conversion of the channels D-E. This sequence repeats itself till the MCR[NSTART] bit is reset by software.

In both the modes, at the end of each channel conversion an End Of Conversion interrupt is issued (if enabled by the corresponding mask bit) and at the end of the conversion sequence an End Of Chain interrupt is issued (if enabled by the corresponding mask bit). The End Of Chain interrupt is issued for each pass of scan mode.

40.4.2 Injected channel conversion

A conversion chain can be injected into the ongoing normal conversion configuring the injected mask registers (ICJCMR0–2, TCJCMR, ECJCMR0–3). As normal conversion, each internal, test or external channel can be individually selected. This injected conversion can only be in one-shot mode and interrupts the normal conversion. When an injected conversion is inserted, ongoing channel conversion is aborted and the injected channel request is processed. After the last channel in the injected chain is converted, normal conversion resumes from the channel at which the normal conversion was stopped as shown in the [Figure 466](#).

Figure 466. Injected sample/conversion sequence

The injected conversion can be started as follows:

- By software
 - The injected conversion chain starts when the MCR[JSTART] bit is set. The current conversion is suspended and the injected chain is converted. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed. It is recommended that the injection trigger enable MCR[JTRGEN] bit is reset during conversions started by software. Once injected conversion has started, any further write operation of MCR[JSTART] bit will not have any effect during ongoing conversion and the new request will get enqueued and executed after current injected chain finishes.
- By injection trigger
 - The injection trigger is enabled by setting the JTRGEN bit in MCR. A programmed event (rising, falling or both edges depending on JEDGESEL bitfield of MCR) on the injection external trigger starts the injected conversion and also sets the MSR[JSTART] bit. At the end of the chain, the MSR[JSTART] bit is reset and the normal chain conversion is resumed.
 - When JTRGSEQ bit is set, the injection trigger sequence feature is enabled. In this mode, each valid edge of injection trigger input will convert one analog channel. First valid edge will convert the first analog channel enabled through ICJCMR0–2, TCJCMR, ECJCMR0–3 registers. The next valid edge converts the next enabled analog input and so on. Once all the enabled channels are converted, the channel selection loops back to the first enabled channel for next trigger edge. If the JTRGSEQ is reset, the channel selection is reset again to first channel enabled through ICJCMR0–2, TCJCMR, ECJCMR0–3 registers. If JTRGSEQ is reset before completing the injected chain, the remaining channels are completed in one-shot after receiving next valid trigger edge.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time MSR[JSTART] is reset if the conversion is started by software.

At the end of each injected conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit) and at the end of the sequence an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit).

40.4.3 Abort conversion

Two different abort functions are provided:

- The user can abort the ongoing conversion by setting the ABORT bit in the MCR. The current conversion is aborted and the conversion of the next channel of the chain is immediately started (generating a new start pulse to the SARADC). In the case of an abort operation, the NSTART/JSTART bit remains set and the ABORT bit is reset after the conversion of the next channel starts. The EOC corresponding to the aborted channel is not generated. This behavior is true for normal or triggered/Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported generating an ECH interrupt.
- It is also possible to abort the current chain conversion by setting the ABORTCHAIN bit in the MCR. In that case the behavior of the ADC depends on the MODE bit. In fact, if scan mode is disabled, the NSTART bit is automatically reset together with the ABORTCHAIN bit. Otherwise, if the MODE bit is set to '1', a new chain conversion is

started. The EOC of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

When a chain conversion abort is requested (ABORTCHAIN bit is set) while an injected conversion is running over a suspended Normal conversion, both injected chain and Normal conversion chain are aborted (both the NSTART and JSTART bits are also reset).

40.4.4 Analog conversion timings and reference selection

40.4.4.1 Conversion timings

In order to support different loadings and switching times (in particular for the external channel types) four different Conversion Timing registers are present (CTR0–3). Each conversion timing register contains PRECHG, INPSAMP bitfields to program the required duration for precharging and sampling phases. The selection of these registers for each channel is done by the SAMPSEL bitfield of corresponding channel data register.

Precharging phase allows to precharge or discharge the internal capacitor to a fixed internal voltage for duration determined by PRECHG bitfield prior to actual analog channel sampling start. This is useful for resetting information regarding the last converted data. Precharging feature can be enabled or disabled for each channel by programming the PCE bit of corresponding channel data register. If precharging is enabled for a given channel, the normal sequence of operation will be precharging, sampling followed by evaluation as shown in [Figure](#) . Please refer to device datasheet for the minimum precharge and sample durations required.

Figure 467. Analog conversion sequence

Bitfields PRECHG, INPSAMP are used to define the total conversion duration (t_{conv}) and in particular the partition among precharge duration (t_{prechg}), sampling phase duration (t_{sample}) and evaluation phase duration (t_{eval}).

The precharging phase duration is given by

$$t_{prechg} = \text{PRECHG} * t_{ck}$$

where PRECHG must be greater than or equal to 2 (hardware requirement) and PCE bit of channel data register is '1'. In case the value of PRECHG is found to be less than 2, it is automatically set to 2 inside SARADC. If the PCE bit is '0', the precharging phase is skipped and conversion starts with sampling phase directly.

The sampling phase duration is given by the following equation:

$$t_{sample} = \text{INPSAMP} * t_{ck}$$

where INPSAMP must be greater than or equal to 4 (hardware requirement). In case the value of INPSAMP is found to be less than 5, it is automatically set to 5 inside SARADC.

The total evaluation phase duration is given by the following equations:

$$t_{\text{eval}} = 25 * t_{\text{ck}}$$
$$t_{\text{eval}} = 21 * t_{\text{ck}} \text{ (for 10-bit conversion)}$$

In this phase, the internal sampling capacitor is disconnected from the analog channel and ADC estimates the digitized value of the sampled input using successive approximation algorithm. In the evaluation phase, all the bits are estimated sequentially to provide the conversion result.

The total conversion duration is (not including external multiplexing) is given by the following:

$$t_{\text{conv}} = t_{\text{prechg}} + t_{\text{sample}} + t_{\text{eval}}$$

The timings refer to the unit t_{ck} refers to reciprocal of f_{ck} , where f_{ck} = SARADC peripheral clock. Total conversion time is $< 5\mu\text{s}$.

Note: The current implementation of ADCDIG does not support hardware restriction over values of PRECHG and INPSAMP fields. As minimum values for these fields are product specific and need to be managed through software.

40.4.4.2 Alternate reference selection

In order to support different accuracy requirements, a voltage reference can be selected for each channel through REFSEL bit of the corresponding channel data register (for example, ICDRn). For some channels, this bit REFSEL is not software programmable and the selection configuration is fixed based on device-specific requirements.

40.4.5 Test channel connection with internal analog channel

The test channels are meant for monitoring various on-chip analog signals coming from temperature sensor, bandgap, voltage regulator and different voltage levels available on the chip. These analog signals can be interfaced to SARADC through test channels for testing purpose. Test channels are mapped from 96 to 127. Each test channel is controlled in the same way as normal internal channel.

SAR ADC Self Testing method: The test channel [127:124] is also mapped to various V_{ref} voltages (4 voltages) selection switches in the ADCBIAS block, the decoding of these channels to switch on and select a particular V_{ref} voltage is done in SoC level muxing logic. Refer ADC configuration for detailed mapping/control description of Self Test feature.

It is also possible to perform test channel conversions with and without shorting the normal analog channel pin with the internal test voltage. The test channel to internal channel mapping is enabled through top level synthesis parameter `testch_short_intch` vector, if shorting of a particular test channel has to be disabled then parameter should be set to '0' for corresponding test channel. This will result in removal of corresponding TCCAPR registers (see ADCDig IG for more details on `testch_short_intch`). For implemented TCCAPR registers to enable the short between test channel and any internal analog channel, `ESIC_TCHx` bit of TCCAPR0–7 registers should be set. The mapping of test channel to any internal analog channel is determined by the `ICSEL_TCHx` bitfield of TCCAPR0–7 registers.

For analog test channel assignment, refer to the device configuration or ADC configuration section.

After the conversion is performed on a test channel the converted data is stored at two CDR locations at the end of conversion, first location is the CDR belonging to the test channel on

which conversion is performed and second location is the CDR belonging to internal channel on which test channel is mapped.

40.4.6 External channel mapping to internal analog channel

External channels are supposed to be used in conjunction with a given internal analog channel along with an 8:1 external mux outside the device. Each input of the external mux can be mapped to a unique channel number, thus allowing it to perform conversions like any other channel of the ADC. External channels are mapped from 128 to 255.

External channels are implemented in the multiples of 8. Each slice of eight channels can be associated to any physical internal analog channel mapped from 0 to 95. This external-to-internal channel mapping is determined by the ICSEL_ECx_x bitfield of ECMICR0–3 registers. For example, when external multiplexer is planned to be used on internal channel 5, and the external inputs need to be mapped to channels 128 to 135, then this channel number 5 must be written to the ICSEL_ECH128_135 bitfield of the ECMICR0 register. After reset, all external channels are mapped to internal analog channel 0. If a conversion on a single external channel(out of group of 8) mapped to a particular internal channel has to be performed then only that particular channel should be enabled in the Conversion Mask Register (ECNMR or ECJCMR).

After the conversion is performed on a external channel the converted data is stored at two CDR locations at the end of conversion, first location is the CDR belonging to the external channel on which conversion is performed and second location is the CDR belonging to internal channel on which external channel is mapped.

40.4.7 Programmable analog watchdog

The analog watchdogs are used for determining whether the result of the conversion of a channel lies within a given guard area (as shown in the [Figure 468](#)) specified by an upper and a lower threshold value named THRH and THRL respectively.

Figure 468. Analog watchdog guarded area

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value lies outside that guard area, then corresponding threshold violation interrupts are generated. The comparison result is stored as WDGxH and WDGxL bits in the WTISR as explained in [Table 533](#). Depending on the MSKWDGxL and MSKWDGxH mask bits in the WTIMR, an interrupt is generated on threshold violation.

Table 533. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THR _H
0	1	converted data < THR _L
0	0	THR _H ≤ converted data ≤ THR _L

The lower and higher threshold values for the analog watchdog are programmed using THR_HL_R0–15 registers. Analog watchdog functionality for each channel can be enabled independently from ICWENR0–2, TCWENR, ECWEN0–3 registers and can select the watchdog threshold registers (THR_HL_R0–15) to be used by programming ICWSELR0–11, TCWSELR0–3, ECWSELR0–15 registers. The threshold registers selected by WSEL_CHx field of watchdog threshold selection registers will provide the threshold values.

For example, if channel 30 is to be monitored with the threshold values in register THR_HL_R12, then WSEL_CH30 is programmed to select THR_HL_R12 register to provide threshold values. The enabling is done by setting the bit corresponding to channel 30 in ICWENR0 register.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in ICAWORR0–2, TCAWORR, ECAWORR0–3 registers. In this case, a set of threshold registers (THR_HL_R0–15) can be linked to several analog channels. The threshold values to be selected for a channel needs be programmed only once in ICWSELR, TCWSELR, ECWSELR registers.

There is an external trigger output port which provides a single clock cycle pulse to indicate WDG threshold crossover event on a particular WDG (up to 16 trigger outputs for up to 16 WDG instances).

Note: *.If the higher threshold for the analog watchdog is programmed lower than the lower threshold and the converted value is lesser than the lower threshold, then the WDGxL interrupt for the low threshold violation is set, else if the converted value is greater than the lower threshold (consequently also greater than the higher threshold) then the interrupt WDGxH for high threshold violation is set. Thus the user should take care of avoiding that situation as it could lead to misinterpretation of the watchdog interrupts.*

40.4.8 DMA functionality

A Direct Memory Access (DMA) request can be programmed after the conversion of every channel, by setting the respective masking bit in ICDSR0–2, TCDSR and ECDSR0–3 registers. The DMA masking registers must be programmed before starting any conversion. The DMA transfers can be enabled using the DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

40.4.9 Interrupts

The SARADC digital interface generates the following maskable interrupt signals:

- End Of Conversion interrupts
 - NEOC (end of normal conversion of each channel)
 - NECH (end of normal chain)
 - JEOC (end of injected conversion of each channel)
 - JECH (end of injected chain)

The EOC_CH[x] bit of interrupt pending registers (ICIPR0–2, TCIPR, ECIPR0–3) is set when channel x completes the conversion (normal or injection). This pending status is qualified when the corresponding mask bit IM_CH[x] is also set in the interrupt mask registers (ICIMR0–2, TCIMR, ECIMR0–3).

The NEOC interrupt is generated only if the following conditions are met

- ISR[NEOC] bit is set after the normal conversion completion for any channel x.
- IMR[MSKNEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

The JEOC interrupt is generated only if the following conditions are met

- ISR[JEOC] bit is set after the injected conversion completion for any channel x.
- IMR[MSKJEOC] bit is set
- EOC_CH[x], IM_CH[x] bits are set at least for one channel x

It is recommended to clear the NEOC/JEOC/EOCTU bits of ISR and all the individual channel pending bits which are not masked while servicing the interrupt.

The ISR[NECH] bit is set when a normal channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

The ISR[JECH] bit is set when an injected channel conversion chain is completed. This pending status is qualified when the corresponding mask bit IMR[MSKNECH] is also set.

- WDGxL and WDGxH (Watchdog threshold) interrupt requests

The interrupts generated due to the analog watchdog are handled by registers WTISR and WTMR in order to check and enable the interrupt requests to external interrupt controller module. The watchdog interrupt source sets two pending bits WDGxH and WDGxL for each channel being monitored in the WTISR. The interrupt request is generated if at least one of the following conditions are met

- WTISR[WDGxL] bit is set and the corresponding mask bit MSKWDGxL is also set in WTMR for at least one channel.
- WTISR[WDGxH] bit is set and the corresponding mask bit MSKWDGxH is also set in WTMR for at least one channel.

The ISR and WTISR contain the interrupt pending request status flags. In case the user wants to clear a particular interrupt event status, writing a '1' to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all other bits of the ISR must be maintained at '0'.)

The ADC module provides dedicated interrupt outputs for all interrupt sources. Also, all interrupt lines are OR-ed together to provide a single output to the external interrupt controller if a combined interrupt is required.

40.4.10 External decode signals selection and delay

The ADC provides three external decode signals used as select lines for 8:1 external mux. For each set of 8 external channels (for example [CH128:CH135], [CH136:CH143], and so on), the same 3-bit decode signals output will be used to select the inputs of external mux. These external mux select lines change in grey code sequence for each increment of channel selection. This ensures that only one line changes and avoids any current spikes or leakage if more than one line changes simultaneously.

In order to take into account the control switching time of the external analog mux, a Decode Signals Delay register is provided. Writing that register allows programming of the delay between the decoding signal selection and the actual start of conversion.

40.4.11 Power down mode

The SARADC analog block can be put in low current consumption mode by setting the PWDN bit in MCR. This is the default mode after exiting from reset. This state must be exited before starting any operation by resetting the PWDN bit in the MCR. When in powerdown mode, no conversion can be started. Bit ADCSTATUS[0] in the MSR is set only when ADC enters Powerdown mode.

The power-down mode can be requested at any time by setting the PWDN bit in the MCR. If a conversion is ongoing, the SARADC cannot immediately enter the power-down mode. In fact, the SARADC enters power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN bit.

After the power down phase is completed the process ongoing before the power down phase must be restarted manually (by setting the appropriate START bit). Resetting PWDN bit and setting NSTART or JSTART bit during the same cycle is forbidden.

40.5 Memory map and registers

This section provides memory map for the SARADC digital interface.

4. Only available with cross-triggering unit (CTU) feature.

Table 535. MCR field descriptions

Field	Description
0 OWREN	Overwrite enable This bit enables or disables the functionality to overwrite unread converted data in ICDR, TCDR, ECDR registers. 0 Prevents overwrite of unread converted data, new result is discarded 1 Enables converted data to be overwritten by a new conversion
1 WLSIDE	Write left/right-aligned 0 The conversion data in ICDR, TCDR, ECDR registers is written right-aligned. 1 Conversion data is left-aligned (from 15 to (15 – resolution + 1)).
2 MODE	One Shot/Scan 0 One Shot Mode—Configures the normal conversion of one chain. 1 Scan Mode—Configures continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately.
3	Reserved
4 NSTART	Normal Start conversion Setting this bit starts the chain or scan conversion. Resetting this bit during scan mode causes the current chain conversion to finish, then stops the operation. 0 Causes the current chain conversion to finish and stops the operation 1 Starts the chain or scan conversion

Table 535. MCR field descriptions (continued)

Field	Description
5 NTRGEN	Normal trigger enable 0 Normal trigger disabled to start a normal conversion. 1 Normal trigger enabled to start a normal conversion.
6–7 NEDGESEL[1:0]	Normal trigger edge selection 00 Falling edge of normal trigger is selected. 01 Rising edge of normal trigger is selected. 1x Both rising and falling edges of normal trigger are selected.
8 JSTART	Injected Start conversion Setting this bit will start the configured injected analog channels to be converted by software. Resetting this bit has no effect, as the injected chain conversion cannot be interrupted. 0 Writing '0' has no effect. 1 Starts the injected chain conversion
9 JTRGEN	Injection trigger enable 0 Injection trigger disabled for channel injection (injected conversion cannot be started using an injection trigger) 1 Injection trigger enabled for channel injection
10–11 JEDGESEL[1:0]	Injection trigger edge selection 00 Falling edge of injection trigger is selected. 01 Rising edge of injection trigger is selected. 1x Both rising and falling edges of injection trigger are selected.
12 JTRGSEQ	Injection trigger sequence enable 0 Injection trigger sequence mode is disabled. 1 Injection trigger sequence mode is enabled.
13	Reserved Write of any value has no effect; read value is always 0.
14	Reserved
15	Reserved
16 WTRIGOUT	WDG Crossover External Trigger Output This control bit enables the Trigger on every threshold crossover event (crossing of Lower/Upper thresholds) of each WDG monitor to external trigger port (up to 16 ports for up to 16 WDGs). 0 Trigger Outputs disabled 1 Trigger Outputs enabled
17–19	Reserved Write of any value has no effect; read value is always 0.
20–23 JTRGSEL[1:0]	Injection Trigger Input Selection This bitfield selects which trigger input to be selected to start injected conversion. 0000 Trigger input 0 is selected 0001 Trigger input 1 is selected ... 1111 Trigger input 15 is selected.

Table 535. MCR field descriptions (continued)

Field	Description
24 ABORTCHAIN	Abort Chain When this bit is set, the ongoing Chain Conversion is aborted. This bit is reset by hardware as soon as a new conversion is requested. 0 Conversion is not affected 1 Aborts the ongoing chain conversion Note: Behaviour of this request during CTU mode is mentioned in CTU trigger/control mode section.
25 ABORT	Abort Conversion When this bit is set, the ongoing conversion is aborted and a new conversion is invoked. This bit is reset by hardware as soon as a new conversion is invoked. 0 Conversion is not affected 1 Aborts the ongoing conversion Note: Behaviour of this request during CTU mode is mentioned in CTU trigger/control mode section.
26	Reserved
27 FRZ	Freeze This bit enables to stop the SARADC conversions at the end of current channel conversion when SoC enters debug mode. 0 Conversions are not stopped. 1 When SoC enters debug mode, further conversions by SARADC analog block will be stopped. The ongoing channel conversion will be completed and the converted data is stored. When the SoC exits debug mode, SARADC resumes the job that was left before halting the conversions. Changing configuration registers during halted condition may cause a pending operation to fail when normal operation is resumed.
28–29	Reserved
30 EDCSELF	External Decode Channel Format Select (EDCSELF) This bit selects the format for 3-bit output port ipp_decode_extch used as select line for external decode channel 8:1 muxes. The last three bits of external channel number are passed as is (if value 0) or converted to gray code (if value 1) and passed to this port. 0 Binary format. 1 Gray Code format.
31 PWDN	Power-down enable When this bit is set, the analog module is requested to enter Power Down mode. When SARADC status is PWDN, resetting this bit starts SARADC transition to IDLE mode. 0 SARADC is in normal mode 1 SARADC has been requested to power down

ICIPR2	EOC_CH[95:64]

Note: Parameter *num_intch* vector has positional inference for registers ICIPR0–2, such that:

- *num_intch*(*i*) (where *i* = 0 to 31) corresponds to ICIPR0 bit [0 to 31],
- *num_intch*(*i*) (where *i* = 32 to 63) corresponds to ICIPR1 bit [0 to 31],
- and
- *num_intch*(*i*) (where *i* = 64 to 95) corresponds to ICIPR2 bit [0 to 31].

If any *num_intch*(*i*) value is '0', corresponding bit is not implemented and read access returns '0' on that bit location.

Thus,

- if *num_intch*[31:0] is all 0's, register ICIPR0 is not implemented.
- if *num_intch*[63:32] is all 0's, register ICIPR1 is not implemented.
- if *num_intch*[95:64] is all 0's, register ICIPR2 is not implemented.

Each is treated as reserved space; any access on this space generates a transfer error.

40.5.1.5 Interrupt Mask Register (IMR)

The description of the Interrupt Mask Register is given below.

Figure 473. Interrupt Mask Register (IMR)

Offset 0x020												Access: User Read/Write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	MSKEOCTU ⁽¹⁾	MSKJEOC	MSKJECH	MSKNEOC	MSKNECH
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Only available with cross-triggering unit (CTU) feature.

Table 540. IMR field descriptions

Field	Description
0–26	Reserved Write of any value has no effect; read value is always 0.
27	Reserved
28 MSKJEOC	Mask bit for JEOC 0 JEOC interrupt is disabled. 1 JEOC interrupt is enabled.
29 MSKJECH	Mask bit for JECH 0 JECH interrupt is disabled. 1 JECH interrupt is enabled.
30 MSKNEOC	Mask bit for NEOC 0 NEOC interrupt is disabled. 1 NEOC interrupt is enabled.
31 MSKNECH	Mask bit for NECH 0 NECH interrupt is disabled. 1 NECH interrupt is enabled.

40.5.1.6 Internal Channel Interrupt Mask Registers 0–2 (ICIMR0–2)

The interrupt mask register to channel association is described in [Table 542](#).

Figure 474. Internal Channel Interrupt Mask Registers (ICIMR0–2)**Table 541. ICIMR0–2 field descriptions**

Field	Description
0–31 IM_CH[x]	IM_CH[x]: Interrupt mask bit for channel x 0 Interrupt for CH[x] is disabled. 1 Interrupt for CH[x] is enabled.

Table 542. Interrupt Mask Registers to Channel Association

Register	Register bits 31:0
ICIMR0	IM_CH[31:0]
ICIMR1	IM_CH[63:32]
ICIMR2	IM_CH[95:64]

Note: Parameter `num_intch` vector has positional inference for registers ICIMR0–2, such that

- `num_intch(i)` (where $i = 0$ to 31) corresponds to ICIMR0 bit [0 to 31],
- `num_intch(i)` (where $i = 32$ to 63) corresponds to ICIMR1 bit [0 to 31],

and

- `num_intch(i)` (where $i = 64$ to 95) corresponds to ICIMR2 bit [0 to 31].

If any of the `num_intch(i)` value is '0' corresponding bit is not implemented and read access would return '0' on that bit location.

Thus,

- if `num_intch[31:0]` is all 0's, register ICIMR0 is not implemented,
- if `num_intch[63:32]` is all 0's, register ICIMR1 is not implemented

and similarly

- if `num_intch[95:64]` is all 0's, register ICIMR2 is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.7 Watchdog Threshold Interrupt Status Register (WTISR)

This register gives the interrupt status information for the 16 possible upper/lower threshold limits monitored by upto 16 watchdog monitors which can be selected for each channel.

Figure 475. Watchdog Threshold Interrupt Status Register (WTISR)

Table 549. CTR0–3 field descriptions

Field	Description
0 CRES	Conversion Resolution select This bit selects the conversion resolution for the conversion. 0: 12-bit resolution 1: 10-bit resolution
1–19	Reserved Write of any value has no effect; read value is always 0.
20–23 PRECHG	Precharging phase duration This bitfield defines the precharging phase duration to be applied when this phase is enabled by PCE bit of channel data register. This duration is calculated as (PRECHG X 1/Frequency of SARADC clock). Please refer to device datasheet for the minimum duration required for precharging phase.
24–31 INPSAMP	Sampling phase duration This bitfield defines the sampling phase duration to be applied. This duration is calculated as (INPSAMP X 1/Frequency of SARADC clock). Please refer to device datasheet for the minimum duration required for sampling phase.

40.5.1.13 Internal Channel Normal Conversion Mask Registers 0–2 (ICNCMR0–2)

The normal conversion mask registers to channel association is described in [Table 551](#).

Figure 481. Internal Channel Normal Conversion Mask Registers (ICNCMR0–2)

Table 550. ICNCMR0–2 field descriptions

Field	Description
0–31 NCE_CH[x]	Normal conversion enable for channel x 0 Normal conversion is disabled for CH[x]. 1 Normal conversion is enabled for CH[x].

Table 551. Internal Channel Normal Conversion Mask Registers to Channel Association

Register	Register bits 31:0
ICNCMR0	NCE_CH[31:0]
ICNCMR1	NCE_CH[63:32]
ICNCMR2	NCE_CH[95:64]

Note: Parameter *num_intch* vector has positional inference for registers ICNCMR0–2, such that

- *num_intch(i)* (where *i* = 0 to 31) corresponds to ICNCMR0 bit [0 to 31],
- *num_intch(i)* (where *i* = 32 to 63) corresponds to ICNCMR1 bit [0 to 31]

and

- *num_intch(i)* (where *i* = 64 to 95) corresponds to ICNCMR2 bit [0 to 31].

If any of the *num_intch(i)* value is '0' corresponding bit is not implemented and read access would return '0' on that bit location.

Thus

- if *num_intch*[31:0] is all 0's, register ICNCMR0 is not implemented
- if *num_intch*[63:32] is all 0's, register ICNCMR1 is not implemented

and similarly

- if *num_intch*[95:64] is all 0's, register ICNCMR2 is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.14 Internal Channel Injected Conversion Mask Registers 0–2 (ICJCMR0–2)

The injected conversion mask registers to channel association is described in [Table 553](#).

Figure 482. Internal Channel Injected Conversion Mask Registers (ICJCMR0–2)**Table 552. ICJCMR0–2 field descriptions**

Field	Description
0–31 JCE_CH[x]	JCE_CH[x]: Injected conversion enable for channel x 0 Injected conversion is disabled for CH[x]. 1 Injected conversion is enabled for CH[x].

Table 553. Internal Channel Normal Conversion Mask Registers to Channel Association

Register	Register bits 31:0
ICJCMR0	JCE_CH[31:0]
ICJCMR1	JCE_CH[63:32]
ICJCMR2	JCE_CH[95:64]

Note: Parameter *num_intch* vector has positional inference for registers ICJCMR0–2, such that

- *num_intch(i)* (where *i* = 0 to 31) corresponds to ICJCMR0 bit [0 to 31],
- *num_intch(i)* (where *i* = 32 to 63) corresponds to ICJCMR1 bit [0 to 31]

and

- *num_intch(i)* (where *i* = 64 to 95) corresponds to ICJCMR2 bit [0 to 31].

If any of the *num_intch(i)* value is '0' corresponding bit is not implemented and read access would return '0' on that bit location.

Thus,

- if *num_intch*[31:0] is all 0's, register ICJCMR0 is not implemented,
- if *num_intch*[63:32] is all 0's, register ICJCMR1 is not implemented

and similarly

- if *num_intch*[95:64] is all 0's, register ICJCMR2 is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.15 Power Down Exit Delay Register (PDEDR)

Figure 483. Power Down Exit Delay Register (PDEDR)

R	0	0	0	0	0	0	0	0	PDED							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 554. PDEDR field descriptions

Field	Description
0–23	Reserved Write of any value has no effect; read value is always 0.
24–31 PDED	PDED: Power down exit delay duration. Defines the delay between the power-down bit reset and the starting of conversion. The power-down delay is calculated as $[PDED \times 1/(SARADC \text{ clock frequency})]$.

40.5.1.16 Internal Channel Data Registers 0–95 (ICDR0–95)

The conversion results for each channel is loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid and some control information to select the required reference voltage, timing parameter selection for each channel.

Figure 484. Internal Channel Data Registers (ICDR0–95)

Offset ICDR0–95: 0x100–0x27C

Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 555. ICDR0–95 field descriptions

Field	Description
0	Reserved Write of any value has no effect; read value is always 0.
1 REFSEL	Reference selection This bit can be used to select the reference voltage for channel conversion. 0 Selects the default reference (e.g., : 5 V) 1 Selects the alternate reference (e.g., : 2 V)
2–3	Reserved Write of any value has no effect; read value is always zero.
4 PCE	<i>Precharge Enable</i> This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled 1 Precharge phase is enabled
5	Reserved. Write of any value has no effect; read value is always zero.
6–7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
8–11	Reserved Write of any value has no effect; read value is always 0.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.

Table 555. ICDR0–95 field descriptions (continued)

Field	Description
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14–15 RESULT[1:0]	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–19	Reserved Write of any value has no effect; read value is always 0.
20–31 CDATA	Channel converted data

Note: The length of the CDATA field depends on the generic resolution.

As each of ICDRx corresponds to an internal channel inferred through generic num_intch. If any of the num_intch(i) is '0', the corresponding ICDRx is not implemented and any access to it generates transfer error. This register should be accessed 32-bit R/W.

The REFSEL bit implementation is dependent on parameter vector altref_exists_ch[95:0].

40.5.1.17 Watchdog Threshold Registers 4–15 (WTHRHLR4–15)

Figure 485. Watchdog Threshold Registers 4–15 (WTHRHLR4–15)

Offset WTHRHLR4–15: 0x280–0x28C																Access: User Read/Write

Table 556. WTHRHLR4–15 field descriptions

Field	Description
0–3	Reserved Write of any value has no effect; read value is always 0.
4–15 THRH	High threshold value for channel x
16–19	Reserved Write of any value has no effect; read value is always 0.
20–31 THRL	Low threshold value for channel x

Note: The number of WTHRHLR registers depends on num_watchdog generic parameter configuration.

In case num_watchdog is zero, these registers are not implemented.

The length of the threshold field depends on the generic resolution.

40.5.1.18 Internal Channel Watchdog Select Registers (ICWSELR0–11)

These registers contain WSEL_CHx[3:0] bitfields to select the threshold register which provides the values to be used for upper and lower bounds for channel x.

The Watchdog select registers to channel association is described in [Table 558](#).

Figure 486. Internal Channel Watchdog Select Registers (ICWSELR0–11)

Offset ICWSELR0–11: 0x2B0–0x2DC												Access: User Read/Write

Table 558. Internal Channel Watchdog Enable Registers to Channel Association

Register	Register bits 31:0
ICWSELRx (x = 0 to 11)	WSEL_CH[(8*x)+7] .. WSEL_CH[8*x]

Note: Each such nibble (i.e., WSEL_CHx) has positional correspondence to num_intch parameter (each channel has a 1:1 nibble correspondence), so each word ICWSELRx corresponds to eight internal channels, thus requiring total twelve 32-bit registers to cover all 96 internal channels. If the value of any num_intch(i) is '0', the corresponding WSEL_CHx nibble is not implemented.

If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

40.5.1.19 Internal Channel Watchdog Enable Registers 0–2 (ICWENR0–2)

The Watchdog enable registers to channel association is described in [Table 560](#).

Figure 487. Internal Channel Watchdog Enable Registers (ICWENR0–2)

Table 559. ICWENR0–2 field descriptions

Field	Description
0–31 WEN_CH[x]	Watchdog enable for channel x 0 Watchdog feature is disabled for CH[x]. 1 Watchdog feature is enabled for CH[x].

Table 560. Internal Channel Watchdog Enable Registers to Channel Association

Register	Register bits 31:0
ICWER0	WEN_CH[31:0]
ICWER1	WEN_CH[63:32]
ICWER2	WEN_CH[95:64]

Note: Parameter *num_intch* vector has positional inference for registers ICWER0–2, such that:

- *num_intch(i)* (where *i* = 0:31) corresponds to ICWER0 bit [0:31]
- *num_intch(i)* (where *i* = 32:63) corresponds to ICWER1 bit [0:31]

and

- *num_intch(i)* (where *i* = 64:95) corresponds to ICWER2 bit [0:31]

If any *num_intch(i)* value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus,

- if *num_intch*[31:0] is all 0's, register ICWER0 is not implemented,
- if *num_intch*[63:32] is all 0's, register ICWER1 is not implemented

and similarly,

- if *num_intch*[95:64] is all 0's, register ICWER2 is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.20 Internal Channel Analog Watchdog Out of Range Registers 0–2 (ICAWORR0–2)

The analog watchdog registers to channel association is described in [Table 562](#).

Figure 488. Internal Channel Analog Watchdog Out of Range Registers (ICAWORR0–2)

Offset ICAWORR0–2: 0x2F0–0x2F8												Access: User Read Only				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	AWOR_CH[x]															
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	AWOR_CH[x]															
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 561. ICAWORR0–2 field descriptions

Field	Description
0–31 AWOR_CH[x]	AWOR_CH[x]: Analog watchdog out of range status for channel x, provided corresponding WEN_CHx bit is set. 0 CH[x] converted data is not out of range determined by its thresholds. 1 CH[x] converted data is out of range determined by its thresholds.

Note: In case either num_watchdog is zero, these registers are not implemented.

Table 562. Internal Channel Analog Watchdog Registers to Channel Association

Register	Register bits 31:0
ICAWORR0	AWOR_CH[31:0]
ICAWORR1	AWOR_CH[63:32]
ICAWORR2	AWOR_CH[95:64]

Note: Parameter num_intch vector has positional inference for registers ICAWORR0–2, such that

- num_intch(i) (where i = 0:31) corresponds to ICAWORR0 bit [0:31]
- num_intch(i) (where i = 32:63) corresponds to ICAWORR1 bit [0:31]

and

- num_intch(i) (where i = 64:95) corresponds to ICAWORR2 bit [0:31]

If any of the num_intch(i) value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus,

- if num_intch[31:0] is all 0's, register ICAWORR0 is not implemented
- if num_intch[63:32] is all 0's, register ICAWORR1 is not implemented

and similarly,

- if num_intch[95:64] is all 0's, register ICAWORR2 is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.21 Test Channel Interrupt Pending Register (TCIPR)

The interrupt channel register to channel association is described in [Table 539](#).

Figure 489. Test Channel Interrupt Pending Register (TCIPR)

Table 563. TCIPR field descriptions

Field	Description
0–31 EOC_CH[x]	End of conversion interrupt pending bit for channel x 0 End of conversion for CH[x] has not occurred. 1 End of conversion for CH[x] has occurred.

Table 564. TCIPR Register to Channel Association

Register	Register bits 31:0
TCIPR	EOC_CH[127:96]

Note: Parameter *num_testch* vector has positional inference for registers *TCIPR*, such that *num_testch(i)* (where *i* = 0:31) corresponds to *TCIPR* bit [0:31].

If any of the *num_testch(i)* value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if *num_testch* is all 0's, register *TCIPR* is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.22 Test Channel Interrupt Mask Registers (TCIMR)

The interrupt mask register to channel association is described in [Table 542](#).

Figure 490. Test Channel Interrupt Mask Registers (TCIMR)

Table 565. TCIMR field descriptions

Field	Description
0–31 IM_CH[x]	IM_CH[x]: Interrupt mask bit for channel x 0 Interrupt for CH[x] is disabled. 1 Interrupt for CH[x] is enabled.

Table 566. Test Channel Interrupt Mask Register to Channel Association

Register	Register bits 31:0
TCIMR	IM_CH[127:96]

Note: *Parameter num_testch vector has positional inference for registers TCIMR, such that num_testch(i) (where i = 0:31) corresponds to TCIMR bit [0:31].*

If any of the num_testch(i) value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if the complete num_testch is all 0's, TCIMR is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.23 Test Channel DMA Select Register (TCDSR)

The DMA select registers to channel association is described in [Table 547](#).

Figure 491. Test Channel DMA Select Register (TCDSR)

Table 567. TCDSR field descriptions

Field	Description
0–31 DS_CH[x]	DMA select for channel x 0 CH[x] is disabled to transfer data in DMA mode. 1 CH[x] is enabled to transfer data in DMA mode.

Table 568. Test Channel DMA Select Registers to Channel Association

Register	Register bits 31:0
TCDSR	DS_CH[127:96]

Note: *Parameter num_testch vector has positional inference for register TCDSR, such that num_testch(i) (where i = 0:31) corresponds to TCDSR bit [0:31].*

If any of the num_testch(i) value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if the complete num_testch is all 0's, TCDSR is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.24 Test Channel Normal Conversion Mask Register (TCNCMR)

The normal conversion mask register to channel association is described in [Table 551](#).

Figure 492. Test Channel Normal Conversion Mask Registers (TCNCMR)

Table 569. TCNCMR field descriptions

Field	Description
0–31 NCE_CH[x]	Normal conversion enable for channel x 0 Normal conversion is disabled for CH[x]. 1 Normal conversion is enabled for CH[x].

Table 570. Test Channel Normal Conversion Mask Register to Channel Association

Register	Register bits 31:0
TCNCMR	NCE_CH[127:96]

Note: *Parameter num_testch vector has positional inference for registers TCNCMR, such that num_testch(i) (where i = 0:31) corresponds to TCNCMR bit [0:31].*

If any of the num_testch(i) value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if the complete num_testch is all 0's, TCNCMR is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.25 Test Channel Injected Conversion Mask Register (TCJCMR)

The injected conversion mask register to channel association is described in [Table 572](#).

Figure 493. Test Channel Injected Conversion Mask Register (TCJCMR)**Table 571. TCJCMR field descriptions**

Field	Description
0–31 JCE_CH[x]	JCE_CH[x]: Injected conversion enable for channel x 0 Injected conversion is disabled for CH[x]. 1 Injected conversion is enabled for CH[x].

Table 572. Test Channel Normal Conversion Mask Register to Channel Association

Register	Register bits 31:0
TCJCMR	JCE_CH[127:96]

Note: Parameter *num_testch* vector has positional inference for registers, such that *num_testch(i)* (where *i* = 0:31) corresponds to TCJCMR bit [0:31].

If any of the *num_testch(i)* value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if the complete *num_testch* is all 0's, TCJCMR is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.26 Test Channel Watchdog Select Registers 0–3 (TCWSELR0–3)

This register contains WSEL_CHx[3:0] bitfields to select the threshold register which provides the values to be used for upper and lower bounds for channel x.

The Watchdog select register to channel association is described in [Table 558](#).

Figure 494. Test Channels Watchdog Select Registers (TCWSELR)

Offset TCWSELR: 0x414–0x420																Access: User Read/Write			
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 573. TCWSELR field descriptions

Field	Description
4*x+3 : 4*x WSEL_CH[x]	Watchdog select for channel x 0000 THRHLR0 register is selected 0001 THRHLR1 register is selected 0010 THRHLR2 register is selected 1110 THRHLR14 register is selected 1111 THRHLR15 register is selected

Table 574. Test Channel Watchdog Select Registers to Channel Association

Register	Register bits 31:0
TCWSELR0	WSEL_CH[103] .. WSEL_CH[96]
TCWSELR1	WSEL_CH[111] .. WSEL_CH[104]
TCWSELR2	WSEL_CH[119] .. WSEL_CH[112]
TCWSELR3	WSEL_CH[127] .. WSEL_CH[120]

Note: Number of bits implemented for each WSEL_CHx depends on num_watchdog parameter. If num_watchdog > 8, the number of bits implemented will be 4 (i.e. WSEL_CHx[3:0]). If num_watchdog > 4 but <= 8, the number of bits implemented will be 3 (i.e. WSEL_CHx[3] will be reserved). Similarly, if num_watchdog > 1 but <= 4, the number of bits implemented will be 2 (i.e. WSEL_CHx[3:2] will be reserved). If num_watchdog = 1, only 1 bit is present. Each such nibble (i.e., WSEL_CHx) has positional correspondence to num_testch parameter (each channel has a 1:1 nibble correspondence), so each word TCWSELRx corresponds to eight test Channels, thus requiring total four 32-bit registers to cover all 32

test channels. If value of any `num_testch(i)` is '0', the corresponding `WSEL_CHx` nibble is not implemented.

If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

40.5.1.27 Test Channel Watchdog Enable Register (TCWENR)

The Watchdog enable registers to channel association is described in [Table 560](#).

Figure 495. Test Channel Watchdog Enable Register (TCWENR)

Table 575. TCWENR field descriptions

Field	Description
0–31 WEN_CH[x]	Watchdog enable for channel x 0 Watchdog feature is disabled for CH[x]. 1 Watchdog feature is enabled for CH[x].

Table 576. Test Channel Watchdog Enable Registers to Channel Association

Register	Register bits 31:0
TCWENR	WEN_CH[127:96]

Note: Parameter `num_testch` vector has positional inference for registers `TCWENR`, such that `num_testch(i)` (where $i = 0:31$) corresponds to `TCWENR` bit [0:31].

If any of the `num_testch(i)` value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if the complete `num_testch` is all 0's, `TCWENR` is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.28 Test Channel Analog Watchdog Out of Range Registers (TCAWORR)

The analog watchdog registers to channel association is described in [Table 562](#).

Figure 496. Test Channel Analog Watchdog Out of Range Register (TCAWORR)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 577. TCAWORR field descriptions

Field	Description
0–31 AWOR_CH[x]	AWOR_CH[x]: Analog watchdog out of range status for channel x, provided corresponding WEN_CHx bit is set. 0 CH[x] converted data is not out of range determined by its thresholds. 1 CH[x] converted data is out of range determined by its thresholds.

Note: In case either of num_watchdog is zero, these registers are not implemented.

Table 578. Analog Watchdog Register to Channel Association

Register	Register bits 31:0
TCAWORR	AWOR_CH[127:96]

Note: Parameter num_testch vector has positional inference for registers TCAWORR, such that num_testch(i) (where i = 0:31) corresponds to TCAWORR bit [0:31].

If any of the num_testch(i) value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if the complete num_testch is all 0's, TCAWORR is not implemented and treated as reserved space. Any access on this space generates a transfer error.

40.5.1.29 Test Channel Connection with Analog Pin Registers 0–7 (TCCAPR0–7)

Each test channel can be shorted with any internal analog channel using the configuration programmed in these registers.

Test channel short registers to channel association is described in [Table 580](#).

Figure 497. Test Channel Connection with Analog Pin Registers 0–7 (TCCAPR0–7)

For analog test channel assignment, refer to the device configuration or ADC configuration section.

Table 579. Test Channel Connection with Analog Pin Registers 0–7 (TCCAPR0–7) field descriptions

Field (Little Endian MSB = bit 31)	Field (Big Endian MSB = bit 0)	Description
Bit 8x+7 ESIC_TCH[x]	Bit 24-8x ESIC_TCH[x]	Enable short with internal channel for test channel x 0 Test channel x cannot be shorted with internal channel 1 Test channel x can be shorted with internal channel
Bit 8x+6 : 8x ICSEL_TCH[x]	Bit 25-8x : 31-8x ICSEL_TCH[x]	Internal channel selection for short with test channel x

Table 580. Test Channel Short Registers to Channel Association

Register	Register bits 31:0 or 0:31 (arrangement of bit fields left to right)
TCCAPRx (x = 0 to 7)	ESIC_TCH[4*x+3], ICSEL_TCH[4*x+3], ESIC_TCH[4*x+2], ICSEL_TCH[4*x+2], ESIC_TCH[4*x+1], ICSEL_TCH[4*x+1], ESIC_TCH[4*x], ICSEL_TCH[4*x]

Note:

- 1) Parameter *num_testch* vector has positional inference for registers *TCCAPRx*, such that
 - *num_testch(i)* (where *i* = 0:3) corresponds to *TCCAPR0*,
 - *num_testch(i)* (where *i* = 4:7) corresponds to *TCCAPR1*,
 - and so on through
 - *num_testch(i)* (where *i* = 28:31) corresponds to *TCCAPR7*.

If all the `num_testch[3:0]` values are '0', the `TCCAPR0` word is not implemented, and so on, up to if all `num_testch[31:28]` values are '0' `TCCAPR7` word is not implemented and treated as reserved space. Any access on this space generates a transfer error.

2) An additional parameter `testch_short_intch` vector also has positional inference for registers `TCCAPRx`, such that

- `testch_short_intch(0)` corresponds to `TCCAPR0[7:0]`,
- `testch_short_intch(1)` corresponds to `TCCAPR0[15:8]`,
- `testch_short_intch(2)` corresponds to `TCCAPR0[23:16]`,
- and so on through
- `testch_short_intch(31)` corresponds to `TCCAPR7[31:24]`.

If `testch_short_intch(0)` value is '0' `TCCAPR0[7:0]` byte is not implemented and so on, up to if `testch_short_intch(31)` value is '0' `TCCAPR7[31:24]` byte is not implemented and treated as reserved space.

3) Parameter `num_testch` has higher precedence than `testch_map_enable`. For e.g. if `num_testch[3:0] = '0011'` and `testch_map_enable[3:0] = '1101'`, only `TCCAPR0[7:0]` byte will be implemented.

40.5.1.30 Test Channel Data Register 96–127 (TCDR96–127)

The conversion results for each channel is loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid and some control information to select the required reference voltage, timing parameter selection for each channel.

Figure 498. Test Channel Data Registers (TCDR96–127)

Offset TCDR96–127: 0x450–0x4CC

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 581. TCDR96–127 field descriptions

Field	Description
0	Reserved Write of any value has no effect; read value is always 0.
1 REFSEL	Reference selection This bit can be used to select the reference voltage for channel conversion. 0 Selects the default reference (for e.g., : 5V) 1 Selects the alternate reference (for e.g., : 2V)
2–3	Reserved. Write of any value has no effect; read value is always zero.
4 PCE	<i>Precharge Enable</i> This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled 1 Precharge phase is enabled
5	Reserved. Write of any value has no effect; read value is always zero.
6–7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
8–11	Reserved Write of any value has no effect; read value is always 0.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14–15 RESULT[1:0]	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–19	Reserved Write of any value has no effect; read value is always 0.
20–31 CDATA	Channel converted data

Note: The length of the CDATA field depends on the generic resolution. As each of TCDRx corresponds to a test channel inferred through generic num_testch. If any of the num_testch(i) is '0', the corresponding TCDRx is not implemented and any access to it generates a transfer error. These registers are accessed 32-bit R/W.
The REFSEL bit implementation is dependent on parameter vector altref_exists_ch[127:96].

40.5.1.31 External Channel Decode Signals Delay Register (ECDSDR)

Figure 499. External Channel Decode Signals Delay Register (ECDSDR)

0–31 EOC_CH[x]	End of conversion interrupt pending bit for channel x 0 End of conversion for CH[x] has not occurred. 1 End of conversion for CH[x] has occurred.

Table 584. ECIPR0–3 Registers to Channel Association

Register	Register bits 31:0
ECIPR0	EOC_CH[159:128]
ECIPR1	EOC_CH[191:160]
ECIPR2	EOC_CH[223:192]
ECIPR3	EOC_CH[255:224]

Note: Parameter `num_extch` vector has positional inference for registers ECIPR0–3, such that

- `num_extch(i)` (where $i = 0:31$) corresponds to ECIPR0 bit [0:31]
- `num_extch(i)` (where $i = 32:63$) corresponds to ECIPR1 bit [0:31]
- `num_extch(i)` (where $i = 64:95$) corresponds to ECIPR2 bit [0:31]

and

- `num_extch(i)` (where $i = 96:127$) corresponds to ECIPR3 bit [0:31].

If any of the `num_extch(i)` value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if any/all of `num_extch[31:0]/[63:32]/[95:64]/[127:96]` is all 0's, the access to corresponding register(s) i.e. ECIPR0/1/2/3 would generate a transfer error.

40.5.1.33 External Channel Interrupt Mask Registers 0–3 (ECIMR0–3)

The interrupt mask register to channel association is described in [Table 542](#).

Figure 501. External Channel Interrupt Mask Registers (ECIMR0–3)**Table 585. ECIMR0–3 field descriptions**

Field	Description
0–31 IM_CH[x]	IM_CH[x]: Interrupt mask bit for channel x 0 Interrupt for CH[x] is disabled. 1 Interrupt for CH[x] is enabled.

Table 586. External Channel Interrupt Mask Registers to Channel Association

Register	Register bits 31:0
ECIMR0	IM_CH[159:128]
ECIMR1	IM_CH[191:160]
ECIMR2	IM_CH[223:192]
ECIMR3	IM_CH[255:224]

Note: Parameter `num_extch` vector has positional inference for registers ECIMR0–3, such that

- `num_extch(i)` (where $i = 0:31$) corresponds to ECIMR0 bit [0:31]
- `num_extch(i)` (where $i = 32:63$) corresponds to ECIMR1 bit [0:31]
- `num_extch(i)` (where $i = 64:95$) corresponds to ECIMR2 bit [0:31]

and

- `num_extch(i)` (where $i = 96:127$) corresponds to ECIMR3 bit [0:31].

If any of the `num_extch(i)` value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if any/all of `num_extch[31:0]/[63:32]/[95:64]/[127:96]` is all 0's, access to corresponding register(s) i.e. ECIMR0/1/2/3 would generate a transfer error.

40.5.1.34 External Channel DMA Select Registers 0–3 (ECDSR0–3)

The DMA select registers to channel association is described in [Table 547](#).

Figure 502. External Channel DMA Select Registers (ECDSR0–3)**Table 587. ECDSR0–3 field descriptions**

Field	Description
0–31 DS_CH[x]	DMA select for channel x 0 CH[x] is disabled to transfer data in DMA mode. 1 CH[x] is enabled to transfer data in DMA mode.

Table 588. DMA Select Registers to Channel Association

Register	Register bits 31:0
ECDSR0	DS_CH[159:128]
ECDSR1	DS_CH[191:160]
ECDSR2	DS_CH[223:192]
ECDSR3	DS_CH[255:224]

Note: Parameter `num_extch` vector has positional inference for registers ECDSR0–3, such that

- `num_extch(i)` (where $i = 0:31$) corresponds to ECDSR0 bit [0:31]
- `num_extch(i)` (where $i = 32:63$) corresponds to ECDSR1 bit [0:31]
- `num_extch(i)` (where $i = 64:95$) corresponds to ECDSR2 bit [0:31]

and

- `num_extch(i)` (where $i = 96:127$) corresponds to ECDSR3 bit [0:31].

If any of the `num_extch(i)` value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if any/all of `num_extch[31:0]/[63:32]/[95:64]/[127:96]` is all 0's, the access to corresponding register(s) i.e. ECDSR0/1/2/3 would generate a transfer error.

40.5.1.35 External Channel Normal Conversion Mask Registers 0–3 (ECNCMR0–3)

The normal conversion mask registers to channel association is described in [Table 551](#).

Figure 503. External Channel Normal Conversion Mask Registers (IECNCMR0–3)

Table 589. ECNCMR0–3 field descriptions

Field	Description
0–31 NCE_CH[x]	Normal conversion enable for channel x 0 Normal conversion is disabled for CH[x]. 1 Normal conversion is enabled for CH[x].

Table 590. External Channel Normal Conversion Mask Registers to Channel Association

Register	Register bits 31:0
ECNCMR0	NCE_CH[159:128]
ECNCMR1	NCE_CH[191:160]
ECNCMR2	NCE_CH[223:192]
ECNCMR3	NCE_CH[255:224]

Note: Parameter *num_extch* vector has positional inference for registers ECNCMR0–3, such that

- *num_extch(i)* (where *i* = 0:31) corresponds to ECNCMR0 bit [0:31]
- *num_extch(i)* (where *i* = 32:63) corresponds to ECNCMR1 bit [0:31]
- *num_extch(i)* (where *i* = 64:95) corresponds to ECNCMR2 bit [0:31]

and

- *num_extch(i)* (where *i* = 96:127) corresponds to ECNCMR3 bit [0:31].

If any of the *num_extch(i)* value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if any/all of *num_extch*[31:0]/[63:32]/[95:64]/[127:96] is all 0's, the access to corresponding register(s) i.e. ECNCMR0/1/2/3 would generate a transfer error.

40.5.1.36 External Channel Injected Conversion Mask Registers 0–3 (ECJCMR0–3)

The injected conversion mask registers to channel association is described in [Table 592](#).

Figure 504. External Channel Injected Conversion Mask Registers (ECJCMR0–3)**Table 591. ECJCMR0–3 field descriptions**

Field	Description
0–31 JCE_CH[x]	JCE_CH[x]: Injected conversion enable for channel x 0 Injected conversion is disabled for CH[x]. 1 Injected conversion is enabled for CH[x].

Table 592. External Channel Normal Conversion Mask Registers to Channel Association

Register	Register bits 31:0
ECJCMR0	JCE_CH[159:128]
ECJCMR1	JCE_CH[191:160]
ECJCMR2	JCE_CH[223:192]
ECJCMR3	JCE_CH[255:224]

Note: Parameter *num_extch* vector has positional inference for registers ECJCMR0–3, such that

- *num_extch(i)* (where *i* = 0:31) corresponds to ECJCMR0 bit [0:31]
- *num_extch(i)* (where *i* = 32:63) corresponds to ECJCMR1 bit [0:31]
- *num_extch(i)* (where *i* = 64:95) corresponds to ECJCMR2 bit [0:31]

and

- *num_extch(i)* (where *i* = 96:127) corresponds to ECJCMR3 bit [0:31].

If any of the *num_extch(i)* value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

Thus, if any/all of *num_extch*[31:0]/[63:32]/[95:64]/[127:96] are all 0's, the access to the corresponding register(s) i.e. ECJCMR0/1/2/3 would generate a transfer error.

40.5.1.37 External Channel Watchdog Select Registers (ECWSELR0–15)

These registers contain WSEL_CHx[3:0] bitfields to select the threshold register which provides the values to be used for upper and lower bounds for channel x.

The Watchdog select registers to channel association is described in [Table 558](#).

Figure 505. External Channel Watchdog Select Registers (ECWSELR0–15)

Offset ECWSELR0–15: 0x0560–0x059C												Access: User Read/Write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 593. ECWSELR0–15 field descriptions

Field	Description
4*x+3 : 4*x WSEL_CH[x]	Watchdog select for channel x 0000: THRHLR0 register is selected 0001: THRHLR1 register is selected 0010: THRHLR2 register is selected 1110: THRHLR14 register is selected 1111: THRHLR15 register is selected

Table 594. External Channel Watchdog Enable Registers to Channel Association

Register	Register bits 31:0
ECWSELRx (x = 0 to 15)	WSEL_CH[(8*x)+135] .. WSEL_CH[(8*x)+128]

Note: Number of bits implemented for each WSEL_CHx depends on num_watchdog parameter:
 If num_watchdog > 8, the number of bits implemented will be 4 (i.e. WSEL_CHx[3:0]).
 If num_watchdog > 4 but <= 8, the number of bits implemented will be 3 (i.e. WSEL_CHx[3] will be reserved).
 Similarly, if num_watchdog > 1 but <= 4, the number of bits implemented will be 2 (i.e. WSEL_CHx[3:2] will be reserved).
 If num_watchdog = 1, then only 1 bit is present.
 Each such nibble (i.e. WSEL_CHx) has positional correspondence to num_extch parameter (each channel has a 1:1 nibble correspondence), so each word ECWSELRx corresponds to

eight external channels, thus requiring a total sixteen 32-bit registers to cover all 128 external channels. If value of any `num_extch(i)` is '0', the corresponding `WSEL_CHx` nibble is not implemented.

If both nibbles in a byte-access, all four nibbles in a halfword-access, and all eight nibbles in a word-access are unimplemented, a transfer error is generated.

40.5.1.38 External Channel Watchdog Enable Registers 0–3 (ECWENR0–3)

The Watchdog enable registers to channel association is described in [Table 560](#).

Figure 506. External Channel Watchdog Enable Registers (ECWENR0–3)

Table 595. ECWENR0–3 field descriptions

Field	Description
0–31 WEN_CH[x]	Watchdog enable for channel x 0 Watchdog feature is disabled for CH[x]. 1 Watchdog feature is enabled for CH[x].

Table 596. External Channel Watchdog Enable Registers to Channel Association

Register	Register bits 31:0
ECWER0	WEN_CH[159:128]
ECWER1	WEN_CH[191:160]
ECWER2	WEN_CH[223:192]
ECWER3	WEN_CH[255:224]

Note: Parameter `num_extch` vector has positional inference for registers ECWER0–3, such that

- `num_extch(i)` (where $i = 0:31$) corresponds to ECWER0 bit [0:31]
- `num_extch(i)` (where $i = 32:63$) corresponds to ECWER1 bit [0:31]
- `num_extch(i)` (where $i = 64:95$) corresponds to ECWER2 bit [0:31],

and

– num_extch(i) (where $i = 96:127$) corresponds to ECWER3 bit [0:31].

If any num_extch(i) value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

If any/all of num_extch[31:0]/[63:32]/[95:64]/[127:96] are '0', the access to corresponding register(s) i.e. ECWER0/1/2/3 would generate a transfer error.

40.5.1.39 External Channel Analog Watchdog Out of Range Registers 0–3 (ECAWORR0–3)

The analog watchdog registers to channel association is described in [Table 562](#).

Figure 507. External Channel Analog Watchdog Out of Range Registers (ECAWORR0–3)

Offset	ECAWORR0–3: 0x05B0–0x05BC												Access: User Read Only

Table 597. ECAWORR0–3 field descriptions

Field	Description
0–31 AWOR_CH[x]	AWOR_CH[x]: Analog watchdog out of range status for channel x, provided corresponding WEN_CHx bit is set. 0 CH[x] converted data is not out of range determined by its thresholds. 1 CH[x] converted data is out of range determined by its thresholds.

Note: In case either num_watchdog is zero, these registers are not implemented.

Table 598. External Channel Analog Watchdog Registers to Channel Association

Register	Register bits 31:0
ECAWORR0	AWOR_CH[159:128]
ECAWORR1	AWOR_CH[191:160]
ECAWORR2	AWOR_CH[223:192]
ECAWORR3	AWOR_CH[255:224]

Note: Parameter `num_extch` vector has positional inference for registers `ECAWORR0–3`, such that

- `num_extch(i)` (where $i = 0:31$) corresponds to `ECAWORR0` bit `[0:31]`
- `num_extch(i)` (where $i = 32:63$) corresponds to `ECAWORR1` bit `[0:31]`
- `num_extch(i)` (where $i = 64:95$) corresponds to `ECAWOERR2` bit `[0:31]`

and

- `num_extch(i)` (where $i = 96:127$) corresponds to `ECAWORR3` bit `[0:31]`.

If any `num_extch(i)` value is '0', the corresponding bit is not implemented and read access would return '0' on that bit location.

If any/all of `num_extch[31:0]/[63:32]/[95:64]/[127:96]` are '0', access to corresponding register(s) i.e. `ECAWORR0/1/2/3` would generate a transfer error.

40.5.1.40 External Channel Mapping to Internal Channel Registers 0–3 (ECMICR0–3)

Each set of eight external channels can be mapped with any internal analog channel using the configuration programmed in these registers.

Figure 508. External Channel Mapping to Internal Channel Registers 0–3 (ECMICR0–3)

Offset ECMICR0–3: 0x5C0–0x05CC																Access: User Read/Write

Table 599. ECMICR0–3 field descriptions

Field	Description
Bit $8x+7$	Reserved Write of any value has no effect; read value is always 0.
Bit $8x+6 : 8x$ ICSEL_ECH	Internal channel selection for external channels $(128 + 8x)$ to $(135+8*x)$ where $x = 0,1,2..16$

Table 600. Test Channel Short Registers to Channel Association

Register	Register bits 31:0
ECMICRx ($x = 0$ to 3)	ICSEL_ECH[$128 + (32*x+31)$] _{128 + (32*x+24)} ICSEL_ECH[$128 + (32*x + 23)$] _{128 + (32*x+16)} , ICSEL_ECH[$128 + (32*x+15)$] _{128 + (32*x+8)} ICSEL_ECH[$128 + (32*x + 7)$] _{128 + 32*x} ,

Note: Parameter `num_extch` vector has positional inference for registers `ECMICR0–3`, such that

- `num_extch(i)` (where $i = 0:31$) corresponds to `ECMICR0`
- `num_extch(i)` (where $i = 32:63$) corresponds to `ECMICR1`
- `num_extch(i)` (where $i = 64:95$) corresponds to `ECMICR2`, and
- `num_extch(i)` (where $i = 96:127$) corresponds to `ECMICR3`.

If any/all of `num_extch[31:0]/[63:32]/[95:64]/[127:96]`, these parameter slices are all '0's, the access to corresponding register(s) i.e. `ECMICR0/1/2/3` would generate a transfer error.

40.5.1.41 External Channel Data Registers 128–255 (ECDR128–255)

The conversion results for each channel is loaded into data registers. Each data register will contain the conversion result, status information related to ADC mode, data valid and some control information to select the required reference voltage, timing parameter selection for each channel.

Figure 509. External Channel Data Registers (ECDR128–255)

Table 601. ECDR128–255 field descriptions

Field	Description
0	Reserved Write of any value has no effect; read value is always 0.
1 REFSEL	Reference selection This bit can be used to select the reference voltage for channel conversion. 0 Selects the default reference (for e.g., : 5 V) 1 Selects the alternate reference (for e.g., : 2 V)
2–3	Reserved. Write of any value has no effect; read value is always zero.
4 PCE	<i>Precharge Enable</i> This bit enables the precharging phase during channel conversion. 0 Precharge phase is disabled 1 Precharge phase is enabled

Table 601. ECDR128–255 field descriptions (continued)

Field	Description
5	Reserved. Write of any value has no effect; read value is always zero.
6–7 CTSEL	This bitfield selects the conversion timing register for each channel to select different precharge and sampling phase durations. 00 CTR0 is selected 01 CTR1 is selected 10 CTR2 is selected 11 CTR3 is selected
8–11	Reserved Write of any value has no effect; read value is always 0.
12 VALID	Data valid flag This bit is used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. 0 Converted data has been read by software. 1 Converted data is valid and has not been read yet.
13 OVERW	Data overwritten flag This bit signals that the previous converted data has been overwritten by a new conversion. This functionality depends on the value of MCR[OWREN]: – When OWREN = 0, OVERW is frozen to 0 and CDATA field is protected against being overwritten until being read. – When OWREN = 1, OVERW flags the CDATA field overwrite status. 0 Converted data has not been overwritten 1 Previous converted data has been overwritten before having been read
14–15 RESULT[1:0]	Conversion result mode status This bit reflects the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–19	Reserved Write of any value has no effect; read value is always 0.
20–31 CDATA	Channel converted data

Note: The length of the CDATA field depends on the generic resolution. As each of ECDRx corresponds to an external channel inferred through generic num_extch. If the value of any num_extch(i) is '0', the corresponding ECDRx is not implemented. Any access on this space generates transfer error. This register should be accessed 32-bit R/W.

The REFSEL bit implementation is dependent on parameter vector altref_exists_ch[255:128].

40.6 Start of conversion pulse delay

The following table lists delays between various trigger point (initiation request for conversion as registered at system clock) and actual issue of start pulse (adc_start) to the ADC hardmacrocell. Here each possible trigger source is described with the number of

Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface

clock cycles required for different operations until trigger of `adc_start`. This table donot take into account any software delay involved in programming or polling of any bit in order to measure conversion timing.

Table 602. Start of conversion pulse delay table

Trigger source	Register control (<code>ipg_clk_s</code>)	Inter domain synchronization (<code>ipg_clk</code>)	ADC state machine (<code>ipg_clk_adc</code>)	Inter domain synchronization (<code>ipg_clk_adc</code>)	Comments
Normal conversion triggered by software (setting of NSTART of MCR)	1	—	2	$1-2^2$	Cumulative Delay from <code>wen(byte_en)</code> assertion to actual issue of <code>adc_start</code> pulse = 3-4 <code>ipg_clk_adc</code> cycles + 1 <code>ipg_clk</code> cycle.
Normal conversion triggered by external trigger (HW trigger through <code>ipp_ind_start_trg</code> port)	—	—	2	$1-2^2$	Cumulative delay from the triggering edge (rising or falling) to the actual issue of <code>adc_start</code> pulse = 3-4 <code>ipg_clk_adc</code> cycles.
Normal conversion within a chain	—	—	0 (from EOC of previous conversion) 1 (from <code>last_evaluation_cyc</code> of previous conversion)	—	Delay from the EOC of last conversion, The start of next conversion is issued exactly on the same cycle when EOC is expected for previous conversion, start pulse in issued looking at <code>last_evaluation_cyc_i</code> which is received one cycle prior to EOC.
Injected conversion triggered by software (setting of JSTART bit of MCR)	1	—	3	$1-2^2$	Cumulative delay from <code>wen(byte_en)</code> assertion. Here delay for first start pulse of the injected chain execution when FSM was originally in IDLE state is considered = 4-5 <code>ipg_clk_adc</code> cycles + 1 <code>ipg_clk</code> cycle.
Injected conversion triggered by external Trigger (HW trigger through <code>ipp_ind_injection_trg</code> port)	—	—	3	$1-2^2$	Cumulative delay from triggering edge (rising or falling) to actual issue of <code>adc_start</code> = 4-5 <code>ipg_clk_adc</code> cycles.

Table 602. Start of conversion pulse delay table (continued)

Trigger source	Register control (ipg_clk_s)	Inter domain synchronization (ipg_clk)	ADC state machine (ipg_clk_adc)	Inter domain synchronization (ipg_clk_adc)	Comments
Injected conversion within a chain (delay between consecutive conversion of injected chain)	—	—	0 (from EOC of previous conversion) 1 (from last_evaluation_cyc of previous conversion)	—	Delay from EOC of last injected channel and adc_start pulse of next injected channel. The start of next conversion is issued exactly on the same cycle when EOC is expected for previous conversion, start pulse is issued looking at last_evaluation_cyc_i which is received one cycle prior to EOC
Injected conversion over normal conversion (software injected conversion chain)	1	1–2 ²	3–5 ¹	1–2 ²	Cumulative delay from wen(byte_en) assertion to actual trigger of first injected channel, when the FSM was in conversion cycle of previous normal conversion = 4–7 ipg_clk_adc cycles + 2–3 ipg_clk cycles.
Injection of conversion over normal conversion in JTRGSEQ mode	—	—	3	1–2 ²	Cumulative delay from triggering edge (rising or falling) to actual issue of adc_start = 4–5 ipg_clk_adc cycles.
Abort of a Normal/Injected Channel conversion during Normal Chain/Injected Chain execution (setting of MCR[ABORT] bit)	1	1–2 ²	3–5 ⁽¹⁾	1–2 ⁽²⁾	Delay from writing of ABORT bit (wen/byte_en assertion) to actual issue of adc_start pulse for the next channel conversion = 4–7 ipg_clk_adc cycles + 2–3 ipg_clk cycles.

1. The above delay values are calculated over a range of system and ADC clock frequencies. With ipg_clk(max) = 50 MHz to ipg_clk(min) = 40 MHz and ipg_clk_adc(max) = 16 MHz to ipg_clk_adc(min) = 14 MHz. L.H.S value corresponds to max frequencies and RHS corresponds to min frequencies.

2. The above variation is owing to inter domain synchronization.

41 Temperature Sensor

41.1 Introduction

SPC57EM80xx MCUs include an onboard temperature sensor that monitors device temperature and delivers one analog output signal and three digital output signals. The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device. The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage, sampled bandgap voltage, which comes from another module, and calibration parameter values stored in internal flash memory. The three digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions. The digital outputs signal when the junction temperature drifts below the low temperature threshold or above one of two high temperature thresholds. These signals notify the device to take action to appropriately adjust the device temperature in response to an out of specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

41.1.1 Signal Descriptions

This module has no external signals.

41.2 Functional description

The temperature sensor generates one analog output voltage, $V_{TSENS}(T)$, which is proportional to the absolute current junction temperature of the device, and three digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or one of two pre-set high temperature thresholds.

An onboard ADC module is used to convert the analog output voltage, as well as the bandgap voltage, into a digital representation. These values, along with parameter values stored in onboard flash memory, are used by software to calculate the device junction temperature.

41.2.1 Temperature threshold detection (digital output generation)

Temperature threshold trimming values are adjusted through calibration during factory test and stored in onboard flash memory. While enabled, if a new trimming value is loaded into the Temperature Sensor module, it may take up to 1 μ s for the digital outputs to be updated reflecting the new trimming condition.

When the temperature threshold detection feature is enabled, the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the three specified temperature thresholds are crossed.

- The low temperature digital output signals if the junction temperature falls below the low temperature threshold ($-40\text{ }^{\circ}\text{C}$).
- The high temperature digital output 1 signals if the junction temperature rises above the first high temperature threshold ($150\text{ }^{\circ}\text{C}$).
- The high temperature digital output 2 signals if the junction temperature rises above the second high temperature threshold ($165\text{ }^{\circ}\text{C}$).

The threshold detection circuit is calibrated in respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to $-40\text{ }^{\circ}\text{C}$) and the high temperature thresholds are trimmed so that one of them matches the hot insertion test temperature (nominally equal to $150\text{ }^{\circ}\text{C}$ or $165\text{ }^{\circ}\text{C}$). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated in [Figure 510](#).

Figure 510. Digital output behavior with temperature

41.2.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an onboard ADC. The temperature value is obtained from a

linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

41.3 Temperature formula

The system chain that translates device junction temperature into a digital variable is comprised of the temperature sensor, a bandgap reference and the onboard ADC. Both the temperature sensor analog output voltage and bandgap reference voltage must be converted by the ADC into digital codes. The temperature formula shown in [Figure 511](#) is used to calculate internal device junction temperature. Note that the formula represents a linear relation between temperature sensor analog output voltage and device junction temperature with calibration adjusted coefficients and ADC reference voltage correction (Bandgap reference terms replaces ADC reference terms in the temperature expression).

Figure 511. Temperature formula

$$T = (232 + TSCA \times 2^{-6}) \times \frac{T_{\text{TSENS_CODE}}(T)}{V_{\text{BG_CODE}}(T)} - (273 + TSCB \times 2^{-4}) \text{ [}^{\circ}\text{C]}$$

Where:

$$TSCA = \left(\frac{T_{\text{HIGH}} - T_{\text{LOW}}}{T_{\text{TSENS_CODE}}(T_{\text{HIGH}}) - T_{\text{TSENS_CODE}}(T_{\text{LOW}})} \times V_{\text{BG_CODE}}(T_{\text{FINAL}}) - 232 \right) \times 2^6$$

$$TSCB = \left(\frac{T_{\text{HIGH}} - T_{\text{LOW}}}{T_{\text{TSENS_CODE}}(T_{\text{HIGH}}) - T_{\text{TSENS_CODE}}(T_{\text{LOW}})} \times T_{\text{TSENS_CODE}}(T_{\text{LOW}}) - T_{\text{LOW}} - 273 \right) \times 2^4$$

$$T_{\text{TSENS_CODE}}(T_{\text{LOW}}) = \frac{V_{\text{TSENS}}(T_{\text{LOW}})}{V_{\text{ref0}}} \times 2^{12}$$

$$T_{\text{TSENS_CODE}}(T_{\text{HIGH}}) = \frac{V_{\text{TSENS}}(T_{\text{HIGH}})}{V_{\text{ref0}}} \times 2^{12}$$

$$V_{\text{BG_CODE}}(T_{\text{FINAL}}) = \frac{V_{\text{BG}}(T_{\text{FINAL}})}{V_{\text{ref0}}} \times 2^{12}$$

$$V_{\text{BG_CODE}}(T) = \frac{V_{\text{BG}}(T)}{V_{\text{ref}}} \times 2^{12}$$

$$T_{\text{TSENS_CODE}}(T) = \frac{V_{\text{TSENS}}(T)}{V_{\text{ref}}} \times 2^{12}$$

Notes:

- TSCA and TSCB are 16-bit signed integer constants stored in flash memory during factory test and calibration
- $V_{\text{TSENS}}(T)$ is the temperature sensor output sampled by the ADC
- $V_{\text{BG}}(T)$ is the bandgap voltage sampled by the ADC at temperature T
- V_{ref} is the ADC reference voltage in normal usage of the device
- V_{ref0} is the ADC reference voltage during factory calibration
- T_{LOW} is the low temperature factory calibration temperature
- T_{HIGH} is the hot temperature factory calibration temperature
- T_{FINAL} is the final insertion factory calibration temperature

Parameters TSCA and TSCB are 16-bit signed integer constants stored during factory test and calibration that need to be used in the temperature formula to calculate device junction temperature. The values for TSCA and TSCB translate into positive or negative shifts of the linear relation coefficients that compensate for manufacturing process variation. [Figure 511](#) shows how parameters TSCA and TSCB are calculated in terms of the actual variables measured during factory calibration.

The calibration points are illustrated in [Figure 512](#).

Figure 512. Calibration Points

41.4 Calculating device temperature

Software must perform the following steps in order to calculate device temperature:

1. Measure the bandgap voltage using the onboard ADC module and calculate $V_{BG_CODE}(T)$ according to the formula shown in [Figure 511](#).
2. Measure the temperature sensor output voltage using the onboard ADC module and calculate $T_{TSENS_CODE}(T)$ according to the formula shown in [Figure 511](#).
3. Retrieve parameters TSCA and TSCB from flash memory.
4. Calculate T according to the formula shown in [Figure 511](#).

Note: Software calculation must be made with negligible precision loss associated with limited bit representation of intermediate calculated results.

42 Timers Overview

Three types of timers are implemented on SPC57EM80xx and a complex timer subsystem.

Table 603. Timers

Timer	Device-specific information	Block details
System Timer Module (STM)	Section 7.7.1: System Timer Module (STM) configuration	Chapter 43: System Timer Module (STM)
Software Watchdog Timer (SWT)	Section 7.7.2: Software Watchdog Timer (SWT) configuration	Chapter 44: Software Watchdog Timer (SWT)
Periodic Interrupt Timer (PIT)	Section 7.7.3: PIT configuration	Chapter 45: Periodic Interrupt Timer (PIT)
GTM103 Wrapper Module Configuration ⁽¹⁾	Section 7.7.4: GTM 103 Integration Module (GTMINT103) configuration	Chapter 88: GTM103 Integration (GTMINT) Module

1. The GTM specification is a separate document that is included in the SPC57EM80xx documentation package.

Each core has a dedicated System Timer Module (STM) and a dedicated Software Watchdog Timer (SWT). The checker core does not have a dedicated STM.

The Secure SWT is on the Hardware Security Module (HSM). It is an enhanced version of the SWT that has the ability to trigger an interrupt not only based on some number of clock cycles, but also based on code executing at some user-defined address. For more information, refer to the *SPC57EM80xx Security Manual*.

Two Periodic Interrupt Timer (PIT) module instances are implemented. One PIT module is for 64-bit timer implementation by way of two 32-bit timer channels (0 and 1) with chaining mode; the timer value is unchanged by a non-destructive reset. The other PIT module is for general use and has eight 32-bit timer channels with no chaining mode.

The GTM103 is an implementation of the Robert Bosch GmbH GTM timer subsystem. It is not a single module; it is a complex timer subsystem that consists of many modules. It can be used to implement highly complex timer functions.

43 System Timer Module (STM)

43.1 Introduction

43.1.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the system clock divided by an 8-bit prescale value (1 to 256).

43.1.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

43.1.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

43.2 External signal description

The STM does not have any external interface signals.

43.3 Memory map and register definition

The STM programming model has fourteen 32-bit registers. The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

43.3.1 Memory map

The STM memory map is shown in [Table 604](#).

Table 604. STM memory map

43.4 Functional description

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel.

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the system clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode the counter continuously increments. When enabled in debug mode the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode, otherwise it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCRn), a channel interrupt register (STM_CIRn) and a channel compare register (STM_CMPn). The channel is enabled by setting the STM_CCRn[CEN] bit. When enabled, the channel will set the STM_CIRn[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing a 1 to the STM_CIRn[CIF] bit. A write of 0 to the STM_CIRn[CIF] bit has no effect.

Note: The STM counter does not advance when the system clock is stopped.

44 Software Watchdog Timer (SWT)

44.1 Introduction

44.1.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires the SWT generates an interrupt or hardware reset. The SWT can be configured to generate a reset or interrupt on an initial time-out. A reset is always generated on a second consecutive time-out.

44.1.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of system or oscillator clock, for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

44.1.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR [on page 1348](#). If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT_CR [on page 1348](#). If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

44.2 External signal description

The SWT module does not have any external interface signals.

44.3 Memory map and register definition

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid access, otherwise a bus error is generated. If either the HLK or

SLK bits in the SWT_CR are set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

The SWT memory map is shown in [Table 610](#). The reset values of SWT_CR and SWT_TO are device specific. These values are determined by SWT inputs.

Table 610. SWT memory map

Offset	Register	Access	Reset Value	Location
0x0000	SWT Control Register (SWT_CR)	R/W	— ⁽¹⁾	on page 1348
0x0004	SWT Interrupt Register (SWT_IR)	R/W	0x0000_0000	on page 1350

0x001C-0x3FFF	Reserved			

1. The reset value for this register is device specific. See the device configuration chapter.

44.3.1 Register descriptions

The following sections detail the individual registers within the SWT programming model.

Note: See the memory map for the base address of SWT registers.

44.3.1.1 SWT Control Register (SWT_CR)

The SWT_CR contains fields for configuring and controlling the SWT. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Figure 518. SWT Control Register (SWT_CR)

1. The reset value for the SWT_CR is device specific. See the device configuration section.

Table 611. SWT_CR field descriptions

Field	Name	Description
0-7	MAPn	Master Access Protection for Master n. The platform bus master assignments are device specific. Not all MAPn fields are implemented. See the device configuration section for master ports that are implemented on the crossbar switch. 0 Access for the master is not enabled 1 Access for the master is enabled
21-22	SMD	Service Mode. 00 Fixed Service Sequence, the watchdog is serviced by writing the fixed sequence 0xA602, 0xB480 to the SWT_SR. 01 Keyed Service Sequence, the watchdog is serviced by writing two pseudorandom key values to the SWT_SR. 10 Fixed Address Execution, the watchdog is serviced by executing code at the address loaded into the designated IAC register which can not be updated while the watchdog is enabled. Support for this mode is device and instance specific. 11 Incremental Address Execution, the watchdog is serviced by executing code at the address loaded into the designated IAC register which can be updated. Support for this mode is device and instance specific.
23	RIA	Reset on Invalid Access. 0 Invalid access to the SWT generates a bus error 1 Invalid access to the SWT causes a system reset if WEN=1
24	WND	Window Mode. 0 Regular mode, service sequence can be done at any time 1 Windowed mode, the service sequence is only valid when the down counter is less than the value in the SWT_WN register.
25	ITR	Interrupt Then Reset. 0 Generate a reset on a time-out 1 Generate an interrupt on an initial time-out, reset on a second consecutive time-out
26	HLK	Hard Lock. This bit is only cleared at reset. 0 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read/write registers if SLK=0 1 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read-only registers
27	SLK	Soft Lock. This bit is cleared by writing the unlock sequence to the service register. 0 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read/write registers if HLK=0 1 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read-only registers
29	STP	Stop Mode Control. Allows the watchdog timer to be stopped when the device enters stop mode. 0 SWT counter continues to run in stop mode 1 SWT counter is stopped in stop mode
30	FRZ	Debug Mode Control. Allows the watchdog timer to be stopped when the device enters debug mode. 0 SWT counter continues to run in debug mode 1 SWT counter is stopped in debug mode
31	WEN	Watchdog Enabled. 0 SWT is disabled 1 SWT is enabled

44.3.1.2 SWT Interrupt Register (SWT_IR)

The SWT_IR contains the time-out interrupt flag.

Figure 519. SWT Interrupt Register (SWT_IR)

1. The reset value of the SWT_TO register is device specific. See the device configuration section.

Table 613. SWT_TO field descriptions

Field	Name	Description
0-31	WTO	Watchdog time-out period in clock cycles. An internal 32-bit down counter is loaded with this value when the service sequence is written or when the SWT is enabled. The initial value is 0x0003_FDE0. The minimum value is 0x0000_0100.

44.3.1.4 SWT Window Register (SWT_WN)

The SWT Window (SWT_WN) register contains the 32-bit window start value. This register is cleared on reset. This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Figure 521. SWT Window Register (SWT_WN)

Table 614. SWT_WN field descriptions

Field	Name	Description
0-31	WST	Window start value. When window mode is enabled, the service sequence can only be written when the internal down counter is less than this value.

44.3.1.5 SWT Service Register (SWT_SR)

The SWT Service (SWT_SR) register is the target for service operation writes used to reset the watchdog timer.

Figure 522. SWT Service Register (SWT_SR)

Table 615. SWT_SR field descriptions

Field	Name	Description
16-31	WSC	Watchdog Service Code. This field is used to service the watchdog and to clear the soft lock bit (SWT_CR[SLK]). If the SWT_CR[KEY] bit is set, two pseudorandom key values are written to service the watchdog, see Section (44.3.1.1) for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the soft lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

44.3.1.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Figure 523. SWT Counter Output Register (SWT_CO)

Table 616. SWT_CO field descriptions

Field	Name	Description
0-31	CNT	Watchdog Count. When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

44.3.1.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT_CR[HCLK] or SWT_CR[SLK] bits are set.

Figure 524. SWT Service Key Register (SWT_SK)

Table 617. SWT_SK field descriptions

Field	Name	Description
16-31	SK	Service Key. This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[KEY] is set, the next key value to be written to the SWT_SR is $(17 \times SK + 3) \bmod 2^{16}$.

44.4 Functional description

The SWT is a 32-bit timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes a control register (SWT_CR), an interrupt register (SWT_IR), a time-out register (SWT_TO), a window register (SWT_WN), a service register (SWT_SR), a counter output register (SWT_CO) and a service key register (SWT_SK).

The SWT_CR register includes bits to enable the timer, set configuration options and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific^(m). If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100 in which case the time-out period is set to 0x100. When the SWT is enabled, this time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. The SWT_CR[CSL] bit selects which clock (system or oscillator) is used to drive the down counter. The reset value of the SWT_TO register is device specific.

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only. The hard lock is enabled by setting the SWT_CR[HCLK] bit, which can only be cleared by a reset. The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register. The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

When enabled, the SWT requires periodic execution of a servicing operation which is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence
- fixed execution address
- incremental execution address

(Some devices or instances only support the fixed service sequence and keyed service sequence modes.) If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected which requires writing 0xA602, 0xB480 to the SWT_SR[WSC] field to service the

m. See SWT section in device configuration chapter.

watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes. If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined in [Figure 525](#). This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 * SK_n + 3) \bmod 2^{16}$$

Figure 525. Pseudorandom Key Generator

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can not be updated while the watchdog is enabled. If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected in which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

If window mode is enabled (SWT_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT_CR[RIA] bit. For example, if the SWT_TO register is set to 5000 and SWT_WN register is set to 1000 then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

The interrupt then reset bit (SWT_CR[ITR]) controls the action taken when a time-out occurs. If the SWT_CR[ITR] bit is not set, a reset is generated immediately on a time-out. If the SWT_CR[ITR] bit is set, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period. If the service sequence is not written before the second consecutive time-out, the SWT generates a system reset. The interrupt is indicated by the time-out interrupt flag (SWT_IR[TIF]). The interrupt request is cleared by writing a one to the SWT_IR[TIF] bit.

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

45 Periodic Interrupt Timer (PIT)

45.1 Introduction

The PIT timer module is an array of timers that can be used to raise interrupts and trigger DMA channels. It includes a dedicated Real Time Interrupt Timer (RTI), which runs on a separate clock and can be used for system wakeup.

Note: For the chip-specific implementation details of this module's instances see the *Device Configuration* chapter.

45.1.1 Block diagram

[Table 526](#) shows the PIT block diagram.

Figure 526. Block diagram of the PIT

Note: Refer to the *Chip Configuration* information for the number of PIT channels used in this MCU.

45.1.2 Features

The main features of this block are:

- One RTI (Real-Time Interrupt) timer to wake up the CPU in Stop mode
- Timers can generate DMA trigger pulses
- Timers can generate interrupts
- All interrupts are maskable
- RTI interrupt can be raised, even when the bus clock is switched off
- Power saving with a separate input clock for the RTI timer (all other timers share one common core clock)
- Independent timeout periods for each timer

45.2 Signal description

This module has no external pins.

45.2.1 Memory map/register description

This section provides a detailed description of all registers accessible in this module.

Note: Reserved registers will read as 0, writes will have no effect.

Note: Refer to the Chip Configuration information for the number of PIT channels used in this MCU.

Note: The RTI registers should be programmed only when the RTI clock is running.

Table 619. PITx_MCR field descriptions

Field	Description
0–28 Reserved	This read-only bitfield is reserved and always has the value zero.
29 MDIS_RTI	Module Disable - RTI section This is used to disable the RTI timer. This bit must be enabled before any RTI setup is done. 0 Clock for RTI timers is enabled. 1 Clock for RTI timers is disabled.
30 MDIS	Module Disable This is used to disable the module clock. The RTI timer is not affected by this bit. This bit must be enabled before any other setup is done. 0 Clock for PIT timers is enabled. 1 Clock for PIT timers is disabled.
31 FRZ	Freeze Allows the timers to be stopped when the device enters debug mode. 0 Timers continue to run in debug mode. 1 Timers are stopped in debug mode.

45.2.1.2 PIT Module x Upper Lifetime Timer Register (PITx_LTMR64H)

The PIT Module x Upper Lifetime Timer Register (PITx_LTMR64H) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

Figure 528. PIT Upper Lifetime Timer Register (PITx_LTMR64H)

Table 620. PITx_LTMR64H field descriptions

Field	Description
0–31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

45.2.1.3 PIT Module x Lower Lifetime Timer Register (PITx_LTMR64L)

The PIT Module x Lower Lifetime Timer Register (PITx_LTMR64L) is intended for applications that chain timer 0 and timer 1 to build a 64-bit life timer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Figure 529. PIT Lower Lifetime Timer Register (PITx_LTMR64L)

Table 621. PITx_LTMR64L field descriptions

Field	Description
0–31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

45.2.1.4 PIT Module x RTI Timer Load Value Register (PITx_RTI_LDVAL)

This register select the timeout period for the timer interrupts.

In the case of the RTI, it takes several cycles until this value is synchronized into the RTI clock domain. For all other timers the value change is visible immediately. The synchronization mechanism allows 0 wait states in this case.

Figure 530. PIT Module x Timer Load Value Register n (PITx_LDVALn)

Table 622. PITx_LDVALn field descriptions

Field	Description
0–31 TSV	Timer Start Value Bits These bits set the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer, instead the value will be loaded once the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again. <i>Note: The RTI timer must not be set to a value lower than 32 cycles, otherwise interrupts may be lost, as it takes several cycles to clear the RTI interrupt. For the other timers, this limit does not apply, however there will be practical limits, since the processor will require several cycles to service an interrupt.</i>

45.2.1.5 PIT Module x RTI Current Timer Value Register (PITx_RTI_CVAL)

This register indicate the current timer position.

For the RTI timers, it shows a value which is several cycles old, since it originates from a potentially different clock domain.

Figure 531. PIT Module x Current Timer Value Register n (PITx_CVALn)

Address: Base + 0x00F4

Access: User read-only

Table 623. PITx_CVALn field descriptions

Field	Description
0–31 TVL	Current Timer Value If the timer is enabled, these bits represent the current timer value. If the timer is disabled, do not use this field as its value is unreliable. <i>Note: The timer uses a down counter. The timer values are frozen in debug mode if the MCR[FRZ] bit is set.</i>

45.2.1.6 PIT Module x RTI Timer Control Register (PITx_RTI_TCTRL)

This register contain the control bits for each timer.

45.3 Functional description

This section provides the functional description of the module.

45.3.1 General

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses as well as to generate interrupts. Each interrupt is available on a separate interrupt line. Additionally the RTI timer can be used to wake up the processor.

45.3.1.1 Timers/RTI

The timers generate triggers at periodic intervals, when enabled. They load their start values, as specified in their LDVAL registers, then count down until they reach 0. Then they load their respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked (by setting the TIE bits in the TCTRL registers). A new interrupt can be generated only after the previous one is cleared. Since in the case of the RTI, clearing the interrupt crosses clock domains, a minimum load value of 32 should be maintained.

If desired, the current counter value of the timer can be read via the CVAL registers. The value of the RTI counter can be delayed considerably, as it is synchronized to the bus clock from the RTI clock domain.

The counter period can be restarted, by first disabling, then enabling the timer with the TEN bit (see the following figure).

Figure 538. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value and then enabling the timer again (see the following figure).

Figure 539. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing the LDVAL register with the new load value. This value will then be loaded after the next trigger event (see the following figure).

Figure 540. Dynamically setting a new load value

45.3.1.2 Debug mode

In debug mode, the timers will be frozen based on field PITx_MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system (for example, the timer values) and then continue the operation.

45.3.2 Interrupts

All of the timers support interrupt generation. The RTI is typically used for system wakeup, but can be used for interrupt generation as well. Refer to the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting the TIE bits. The timer interrupt flags (TIF) are set to 1 when a timeout occurs on the associated timer, and are cleared to '0' by writing a '1' to that TIF bit.

The PIT RTI generates a real time interrupt when the selected interrupt time period elapses. The RTI interrupt is disabled locally by setting the TIE bit to zero. The real time interrupt flag (TIF) is set to '1' when a timeout occurs, and is cleared by writing a '1' to the TIF bit. (The flag will be set regardless whether the interrupt is enabled.)

The RTI can be used for periodic wakeup from a low power mode. It can also be used to generate a general purpose interrupt.

45.3.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer $n-1$ has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

45.4 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- The RTI clock has a frequency of 10 MHz.
- The RTI creates a wakeup interrupt every 500 ms.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

First the PIT module must be activated by writing a 0 to field PITx_MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns and the 10 MHz frequency equates to a clock period of 100 ns. Therefore, the RTI timer needs to trigger every 500 ms/100 ns = 5000000 cycles. Timer 1 needs to trigger every 5.12 ms/20 ns = 256000 cycles and timer 3 every 30 ms/20 ns = 1500000 cycles. The value for the LDVAL register trigger is calculated as:

$LDVAL\ trigger = (period / clock\ period) - 1$

This means RTI_LDVAL will be written with 004C4B3F hex, LDVAL1 should be written with 0x0003E7FF, and LDVAL3 should be written with 0x0016E35F.

To generate the wakeup interrupt, the interrupt line must be enabled by writing a '1' to bit RTI_TCTRL[TIE]. To start the RTI, bit RTI_TCTRL[TEN] must also be set.

The interrupt for Timer 1 is enabled by setting bit TCTRL1[TIE]. The timer is started by writing '1' to bit TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore Timer 3 is started by writing a '1' to bit TCTRL3[TEN]; bit TIE stays at 0.

The following example code matches the described setup:

Example 14

```
// turn on PIT
PIT_MCR = 0x00;

// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // setup RTI for 5000000 cycles
PIT_RTI_TCTRL = PIT_TIE; // let RTI generate interrupts
PIT_RTI_TCTRL |= PIT_TEN; // start RTI

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

45.5 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 hour.

First the PIT module needs to be activated by writing a '0' to field PITx_MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to timer 1 and programmed to trigger every 10 times.

The value for the LDVAL register trigger is calculated as number of cycles –1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for timer 2 is enabled by setting PITx_TCTRL2[TIE], the chain mode is activated by setting CHN, and the timer is started by writing a '1' to PITx_TCTRL2[TEN]. In PITx_TCTRL1, the TEN bit needs to be set, and CHN and TIE bits are cleared.

The following example code matches the described setup:

Example 15

```
// turn on PIT
PIT_CTRL = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain timer 2 to timer 1
PIT_TCTRL2 |= TEN; // start timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup timer 1 for 600 000 000 cycles
PIPIT_TCTRL1 = TEN; // start timer 1
```

45.6 Example Configuration for the Lifetime Timer

To configure the life timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a '0' to field PITx_MCR[MDIS], then the LDVAL registers need to be set to the maximum value.

The following example code matches the described setup:

Example 16

```
// turn on PIT
PIT_CTRL = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 2 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime read first LTMR64H then LTMR64L.

Equation 26 $\text{current_uptime} = \text{PIT_LTMR64H} \ll 64;$

$\text{current_uptime} = \text{current uptime} + \text{PIT_LTMR64L}$

The timer is a down counter.

46 CAN Subsystem

46.1 Introduction

The Controller Area Network (CAN) subsystem consists of the modular CAN (M_CAN) modules and Time triggered CAN (M_TTCAN) modules along with an integrated intelligent CAN RAM controller. The CAN RAM controller consists of additional logic for arbitration between the requests for the RAM access by the various CANs and CPU, ECC encoder/decoder for the Message RAM data and active transmit message buffer protection and M_TTCAN trigger memory from CPU write access. The subsystem follows the little endian format.

Note: Please refer to the Device Configuration chapter to see the number of CAN nodes used in the device.

Table 630. References

IP Name	Version
M_CAN IP	Revision 2.0
M_TTCAN IP	Revision 2.0

The general CAN subsystem implementation is shown in [Figure 541](#). It interfaces with the host processor bus using the peripheral bus. The RAM is not implemented inside the subsystem.

1: Number of M_CAN nodes vary per device. x = 1 to n. Please refer Device Configuration chapter to see the number of M_CAN nodes used in the device.

2: Please refer Device Configuration chapter to see the number of M_TTCAN nodes used in the device.

Figure 541. CAN subsystem generic block diagram

46.2 Features

The CAN subsystem consists of the following major blocks:

- Modular CAN cores: The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- Time triggered CAN core. The registers of the CAN module can be accessed using the Generic Slave Interface (GSI)
- CAN-RAM arbiter
- SRAM interface and memory organization
- ECC Controller
- Transmit message buffer locking mechanism
 - Trigger memory locking

46.3 Modular CAN cores

CAN functionality conforms to CAN specification V2.0B active for each CAN node. The M_CAN performs communication according to the CAN protocol specification 2.0 part A,B and to CAN FD 1.0. Flexible assignment of Message Objects to nodes.

The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for connection to the physical layer.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_CAN via the Generic Master Interface. Depending on the chosen device, multiple M_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_CAN's clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.

46.3.1 Features

The following are the features of Modular CAN cores.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1
- CAN Flexible data-rate (CAN-FD) protocol with maximum 8 data bytes is supported
- Bit rates up to 1 Mbit/s (in standard CAN mode)
- CAN error logging
- AUTOSAR optimized
- SAE J1939 optimized
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8-/16-/32-bits Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug over M_CAN

46.3.2 Block diagram

Figure 542. M_CAN core block diagram

- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Clk: Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.
- Rx Handler: Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored

together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

- Generic Slave Interface: Connects the M_CAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- Generic Master Interface: Connects the M_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32 bits. A single M_CAN can use at most 1 KB × 32 bits.

46.3.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as CAN clock. The CAN core should be programmed to have at least 8 clocks per bit time, this is for example, 1 Mbaud at CAN clock ≥ 8 MHz. Even in case of a very high Host clock frequency, the clock frequency of the CAN core must not be higher than 8 MHz.

Within the M_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: In order to achieve a stable function of the M_CAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.

Caution: Stop this module when the device is in STOP mode. If CAN message reception is mandatory, check that the PLL is unlocked before transmitting any message. Use the external oscillator (XOSC) instead of the internal RC oscillator (IRCOSC) during the STOP mode.

46.3.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to INT 0 or to INT 1. By default all interrupts are routed to interrupt line INT 0. By programming INT 0 and INT 1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

46.3.5 Memory map and register descriptions

46.3.5.1 Hardware reset description

After hardware reset, the registers of the M_CAN hold the reset values listed in [Table 631](#). Additionally the *Bus_Off* state is reset and the M_CAN Tx output is set to *recessive* (HIGH). The value 0x0001 (**bit 0 [INIT]** of the **CCCR register** = '1') in the CC Control Register enables software initialization. The M_CAN does not influence the CAN bus until the CPU resets **bit 0 [INIT]** of the **CCCR register** = '0'.

46.3.5.2 Register map

The M_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

Note: Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when the bit 1 [CCE] and bit 0 [INIT] of the CCCR register is set to “1”.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

46.3.5.2.3 Fast Bit Timing and Prescaler Register (FBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programed in the range of 4 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to 1024 M_CAN clock periods. $tq = (FBRP + 1) M_CAN$ clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. **FTSEG2** is Phase_Seg2.

Therefore the length of the bit time is (prog rammed values) **[FTSEG1 + FTSEG2 + 3]** tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Figure 546. Fast Bit Timing and Prescaler Register

Field	Description
0:3 TDCO	Transceiver Delay Compensation Offset 0x0–0xF— Offset value defining the distance between the measured delay from m_can_tx to m_can_rx and the secondary sample point. Valid values are 0 to 15 M_CAN clock periods.
4 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
6:15 FBRP	Fast Baud Rate Prescaler 0x000–0x3FF— The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
20:23 FTSEG1	Fast time segment before sample point 0x1–0xF— Valid values are 1 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
25:27 FTSEG2	Fast time segment before sample point 0x0–0x7— Valid values are 0 to 7. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
30:31 FSJW	Fast (Re) Synchronization Jump Width 0x0–0x3— Valid values are 0 to 3. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.

46.3.5.2.4 Test Register

Write access to the Test Register has to be enabled by setting CCCR[TEST] to '1'. All Test Register functions are set to their reset values when CCCR[TEST] is reset. Loop Back

mode and software control of M_CAN Tx pin are hardware test modes. Programming of TX ≠ "00" may disturb the message transfer on the CAN bus.

Figure 547. Test Register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 634. Test Register field descriptions

Field	Description
0:14	Reserved
19:23 TDCV	Transceiver Delay Compensation Value 0x00–0x1F— Position of the secondary sample point, defined by the sum of the measured delay from m_can_tx to m_can_rx and FBTP.TDCO. Valid values are 0 to 31 M_CAN core clock periods.
24 RX	Receive Pin Monitors the actual value of pin m_can_rx 0 The CAN bus is dominant (m_can_rx = '0') 1 The CAN bus is recessive (m_can_rx = '1')
25:26 TX	Control of Transmit Pin 00 Reset value, m_can_tx is controlled by the CAN core, updated at the end of the CAN bit time 01 Sample Point can be monitored at pin m_can_tx 10 Dominant ('0') level at pin m_can_tx 11 Recessive ('1') at pin m_can_tx
27 LBCK	Loop Back mode 0 Reset value, Loop Back mode is disabled 1 Loop Back mode is enabled (see Section 46.3.7.8, Test modes)
28:31	Reserved

46.3.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the WDC bits. The counter is reloaded with WDC bits when the Message RAM signals successful completion by activating its READY output. In

case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag WDI bit of the IR register is set. The RAM Watchdog Counter is clocked by the Host clock .

Figure 548. RAM watchdog register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 635. RAM Watchdog register field descriptions

Field	Description
0:15	Reserved
16:23 WDV	Watchdog Value Actual Message RAM Watchdog Counter Value
24:31 WDC	Watchdog Configuration Start value of the Message RAM Watchdog Counter. With the reset value of "00" the counter is disabled.

46.3.5.2.6 CC Control Register (CCCR)

The following section shows the CAN Control register. For details about setting and resetting of single bits see [Section 46.3.7.1.1, Software initialization](#).

Figure 549. CC Control register

Address: 0x0018

Access: Read Protected

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 636. CC Control Register field descriptions

Field	Description
0:15	Reserved
16 LONG	Long Frame Mode Enable 0 Long Frame Mode disabled, LACT may not be set 1 Long Frame Mode enabled, LACT may be set
17 FAST	Fast Frame Mode Enable 0 Fast Frame Mode disabled, FACT may not be set 1 Fast Frame Mode enabled, FACT may be set if Long Frame Mode also enabled
18 LACT	Long Frame Mode Active 0 Frames transmitted in Standard CAN format 1 Frames transmitted in CAN FD Long format
19 FACT	Fast Frame Mode Active 0 Format of transmitted frames defined by LACT 1 Frames transmitted in CAN FD Fast format
20 CLRL	Clear Long Frame Mode 0 Not waiting for deactivation of Long Frame Mode 1 Waiting for deactivation of Long Frame Mode
21 SETL	Set Long Frame Mode 0 Long Frame Mode active or not requested 1 Waiting for activation of Long Frame Mode

Table 636. CC Control Register field descriptions (continued)

Field	Description
22 CLRf	Clear Fast Bit Rate Mode 0 Not waiting for deactivation of Fast Frame Mode 1 Waiting for deactivation of Fast Frame Mode
23 SETf	Set Fast Bit Rate Mode 0 Long Fast Mode active or not requested 1 Waiting for activation of Fast Frame Mode
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_CAN may be set in power down by stopping host clock and core clock
29 ASM	ASM Restricted Operation Mode The Restricted Operation Mode is intended for applications that adapt themselves to different CAN bit rates. The application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame. In the optional Restricted Operation Mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. If the M_CAN is connected to a Clock Calibration on CAN unit, ASM is controlled by input M_CAN calibration OK (m_can_cok) signal. In case m_can_cok switches to '0', bit ASM is set. When m_can_cok switches back to '1', bit ASM returns to the previously written value. The state of ASM is the written value while input m_can_cok is at '1'. The input is hardwired to '1' when there is no Clock Calibration on CAN unit connected. 0 Normal CAN operation 1 Restricted Operation Mode active

Table 636. CC Control Register field descriptions (continued)

Field	Description
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started

Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to ensure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

46.3.5.2.7 Bit Timing and Prescaler Register (BTP)

This register is only writable if bits CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programmed in the range of [4...81] time quanta. The CAN time quantum may be programmed in the range of [1...1024] M_CAN clock periods.

Equation 27 $tq = (BRP + 1) M_CAN \text{ clock period}$

TSEG1 is the sum of Prop_Seg and Phase_Seg1. **TSEG2** is Phase_Seg2.

Therefore the length of the bit time is (programmed values) **[TSEG1 + TSEG2 + 3] tq** or (functional values) **[Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq**.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Figure 550. Bit Timing and Prescaler Register

Address: 0x001C												Access: Read Protected				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0	0	TSEG1 ⁽¹⁾						TSEG2[3:0] ⁽¹⁾				SJW ⁽¹⁾			
W																
Reset	0	0	0	0	1	0	1	0	0	0	1	1	0	0	1	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 637. Bit Timing and Prescaler Field Descriptions

Field	Description
0:5	Reserved
6:15 BRP	Baud Rate Prescaler (0x000–0x3FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16:17	Reserved
18:23 TSEG1	Time segment before sample point (0x01–0x3F) Valid values are 1 to 63. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24:27 TSEG2	The time segment before the sample point (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 SJW	(Re) Synchronization Jump Width (0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a bit rate of 500 kbit/s.

Note: The Information Processing Time (IPT) of the M_CAN is 0 tq. Therefore, to conform to the CAN protocol specification, the lengths for phase segment 1 (Phase_Seg1) and phase segment 2 (Phase_Seg2) must be equal.

46.3.5.2.8 Timestamp Counter Configuration Register (TSCC)

Figure 551. Timestamp Counter Configuration Register

Address: 0x0020

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 638. Timestamp Counter Configuration field descriptions

Field	Description
0:11	Reserved
12:15 TCP	Timestamp Counter Prescaler 0x0–0xF Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1 to 16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. <i>Note: With CAN FD an external counter is required for timestamp generation (TSS = "10")</i>
16:29	Reserved
30:31 TSS	Timestamp Select 00 Timestamp counter value always 0x0000 01 Timestamp counter value incremented according to TCP 10 Reserved 11 Same as "00"

46.3.5.2.9 Timestamp Counter Value Register (TSCV)

Figure 552. Timestamp counter value register

Table 639. Timestamp counter value field descriptions

Field	Description
0:15	Reserved
16:30 TSC	Timestamp Counter The Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC[TSS] = "01", the Timestamp Counter is incremented in multiples of CAN bit times [1...16] depending on the configuration of TSCC[TCP] . A wrap around sets interrupt flag IR[TSW] . Write access resets the counter to zero.

Note: A “wrap around” is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

46.3.5.2.10 Timeout Counter Configuration Register (TOCC)

For a description of the Timeout Counter see [Section 46.3.9, Timeout counter](#).

Figure 553. Timeout counter configuration register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 640. Timeout Counter Configuration Field Descriptions

Field	Description
0:15 TOP[15:0]	Timeout Period Start value of the Timeout Counter (down-counter). Configures the Timeout Period.
16:28	Reserved
29:30 TOS	Timeout Select When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP] . Down-counting is started when the first FIFO element is stored. 00 Continuous operation 01 Timeout controlled by Tx Event FIFO 10 Timeout controlled by Rx FIFO 0 11 Timeout controlled by Rx FIFO 1
31 ETOC	Enable Timeout Counter 0 Timeout Counter disabled 1 Timeout Counter enabled <i>Note: For use of timeout function with CAN FD see Section 46.3.9, Timeout counter.</i>

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Access type is RX: reset on read.

Table 642. Error counter register field descriptions

Field	Description
0:7	Reserved
8:15 CEL	CAN Error Logging The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag ELO bit of the IR register.
16 RP	Receive Error Passive 0 The Receive Error Counter is below the error passive level of 128 1 The Receive Error Counter has reached the error passive level of 128
17:23 REC	Receive Error Counter Actual state of the Receive Error Counter, values between 0 and 127
24:31 TEC	Transmit Error Counter Actual state of the Transmit Error Counter, values between 0 and 255

Note: When *CCCR.ASM* is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

46.3.5.2.13 Protocol Status Register (PSR)

Figure 556. Protocol status register (PSR)

Address: 0x0044

1. Access type is RX: reset on read.

2. Access type is RS: set on read.

Table 643. PSR descriptions

Field	Description
0:17	Reserved
18 REDL	Received CAN FD Message with EDL flag 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with EDL flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21:23 FLEC	Fast Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_CAN is not Bus_Off 1 The M_CAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_CAN is in the Error_Passive state
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing – node is synchronizing on CAN communication 01 Idle—node is neither receiver nor transmitter 10 Receiver—node is operating as receiver 11 Transmitter—node is operating as transmitter

Table 643. PSR descriptions (continued)

Field	Description
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_CAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCErrror: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error

Note: The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it will set CCCR[INIT] of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129×11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit 0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

46.3.5.2.14 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Table 644. Interrupt register field descriptions

Field	Description
0 STE	Stuff Error 0 No Stuff Error detected 1 More than 5 equal bits in a sequence occurred
1 FOE	Format Error 0 No Format Error detected 1 A fixed format part of a received frame has the wrong format
2 ACKE	Acknowledge Error 0 No Acknowledge Error detected 1 A transmitted message was not acknowledged by another node
3 BE	Bit Error 0 No Bit Error detected 1 Device wanted to send a rec / dom level, but monitored bus level was dom / rec
4 CRCE	CRC Error 0 No CRC Error detected 1 Received CRC did not match the calculated CRC
5 WDI	Watchdog Interrupt 0 No Message RAM Watchdog event occurred 1 Message RAM Watchdog event due to missing READY
6 BO	Bus_Off Status 0 Bus_Off status unchanged 1 Bus_Off status changed
7 EW	Warning Status 0 Error_Warning status unchanged 1 Error_Warning status changed

Table 644. Interrupt register field descriptions (continued)

Field	Description
8 EP	Error Passive 0 Error_Passive status unchanged 1 Error_Passive status changed
9 ELO	Error Logging Overflow 0 CAN Error Logging Counter did not overflow 1 Overflow of CAN Error Logging Counter occurred
10 BEU	Bit Error Uncorrected Message RAM bit error detected, uncorrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. An uncorrected Message RAM bit error sets CCCR[INIT] to '1'. This is done to avoid transmission of corrupted data. 0 No bit error detected when reading from Message RAM 1 Bit error detected, uncorrected (e.g. parity logic)
11 BEC	Bit Error Corrected Message RAM bit error detected and corrected. Controlled by Message RAM bit error input signal generated by an optional external parity / ECC logic attached to the Message RAM. 0 No bit error detected when reading from Message RAM 1 Bit error detected and corrected (e.g. ECC)
12 DRX	Message stored to Dedicated Rx Buffer The flag is set whenever a received message has been stored into a dedicated Rx Buffer. 0 No Rx Buffer updated 1 At least one received message stored into a Rx Buffer
13 TOO	Timeout Occurred 0 No timeout 1 Timeout reached
14 UMD	Unprocessed Message Discarded When a new message is received while the acceptance filtering process for the previously received message has not yet completed, this message is discarded. 0 No unprocessed message discarded 1 Unprocessed message discarded
15 TSW	Timestamp Wraparound 0 No timestamp counter wrap-around 1 Timestamp counter wrapped around
16 TEFL	Tx Event FIFO Event Lost 0 No Tx Event FIFO element lost 1 Tx Event FIFO element lost, also set after write attempt to Tx Event FIFO of size zero
17 TEFF	Tx Event FIFO Full
18 TEFW	Tx Event FIFO Watermark Reached 0 Tx Event FIFO fill level below watermark 1 Tx Event FIFO fill level reached watermark

Table 644. Interrupt register field descriptions (continued)

Field	Description
19 TEFN	Tx Event FIDO New Entry 0 Tx Event FIFO unchanged 1 Tx Handler wrote Tx Event FIFO element
20 TFE	Tx FIFO Empty 0 Tx FIFO non-empty 1 Tx FIFO empty
21 TCF	Transmission Cancellation Finished 0 No transmission cancellation finished 1 Transmission cancellation finished
22 TC	Transmission Completed 0 No transmission completed 1 Transmission completed
23 HPM	High Priority Message 0 No high priority message received 1 High priority message received
24 RF1L	Rx FIFO 1 Message Lost 0 No Rx FIFO 1 message lost 1 Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero
25 RF1F	Rx FIFO 1 Full 0 Rx FIFO 1 not full 1 Rx FIFO 1 full
26 RF1W	Rx FIFO 1 Watermark Reached 0 Rx FIFO 1 fill level below watermark 1 Rx FIFO 1 fill level reached watermark
27 RF1N	Rx FIFO 1 New Message 0 No new message written to Rx FIFO 1 1 New message written to Rx FIFO 1
28 RF0L	Rx FIFO 0 Message Lost 0 No Rx FIFO 0 message lost 1 Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero
29 RF0F	Rx FIFO 0 Full 0 Rx FIFO 0 not full 1 Rx FIFO 0 full
30 RF0W	Rx FIFO 0 Watermark Reached 0 Rx FIFO 0 fill level below watermark 1 Rx FIFO 0 fill level reached watermark
31 RF0N	Rx FIFO 0 New Message 0 No new message written to Rx FIFO 0 1 New message written to Rx FIFO 0

46.3.5.2.15 Interrupt Enable Register (IE)

The settings in the Interrupt Enable register determine which status changes in the Interrupt register will be signaled on an interrupt line.

0:8	Reserved
9:15 LSE	List Size Extended 0 No extended Message ID filter 1–64 Number of extended Message ID filter elements >64 Values greater than 64 are interpreted as 64
16:29 FLESA	Filter List Extended Start Address Start address of extended Message ID filter list (32-bit word address, see Figure 585).
30:31	Reserved

46.3.5.2.21 Extended ID and Mask Register (XIDAM)

Figure 564. Extended ID and Mask register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 651. Extended ID and Mask register field descriptions

Field	Description
0:2	Reserved
3:31 EIDM	Extended ID Mask For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active.

46.3.5.2.22 High Priority Message Status Register (HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Figure 565. High Priority Message Status register

Address: 0x0094

Table 664. Tx Buffer Request Pending register field descriptions

Field	Description
0:31 TRP	Transmission Request Pending Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (see Section 46.4.7.15, Tx handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF – after successful transmission together with the corresponding TXBTO bit – when the transmission has not yet been started at the point of cancellation – when the transmission has been aborted due to lost arbitration – when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: *TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.*

46.3.5.2.35 Tx Buffer Add Request Register (TXBAR)

[16:18]	Reserved
[19:23] EFGI	Event FIFO Get Index. Tx Event FIFO read index pointer, range 0 to 31.
[24:25]	Reserved.
[26:31] EFFL	Event FIFO Fill Level. Number of elements stored in Tx Event FIFO, range 0 to 32.

46.3.5.2.43 Tx Event FIFO Acknowledge Register (TXEFA)

Figure 584. Tx Event FIFO Acknowledge register

Table 675. Tx Event FIFO Acknowledge field description

Field	Description
[0:26]	Reserved.
[27:31] EFAI	Event FIFO Acknowledge Index. After the Host has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the FIFO 0 Fill Level TXEFS[EFFL] .

46.3.6 Message RAM

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_CAN module can be configured to allocate up to 1216 words in the Message RAM. It is not necessary to

configure each of the sections listed in the following figure, nor is there any restriction with respect to the sequence of the sections.

Figure 585. Message RAM Configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configured start addresses are 32-bit word addresses.

Note: The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

46.3.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following figure.

Figure 586. Rx FIFO Element

R3 Bits 7:0	DB4[7:0]: Data Byte 4

46.3.6.2 Tx buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC[TFQS] and TXBC[NDTB].

Figure 587. Tx Buffer Element

Table 677. Tx Buffer Element descriptions

T0 Bit 30 XTD: Extended Identifier	0 11-bit standard identifier 1 29-bit extended identifier
T0 Bit 29 RTR: Remote Transmission Request	0 Transmit data frame 1 Transmit remote frame
T0 Bits 28:0 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
T1 Bits 31:24 MM[7:0]: Message Marker	Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.
T1 Bit 23 EFC	Event FIFO Control 0 Don't store Tx events 1 Store Tx events
T1 Bits 19:16 DLC[3:0]	Data Length Code 0-8 Transmit frame with 0-8 data bytes 9-15 Transmit frame with 8 data bytes
T2 Bits 31:24	DB3[7:0]: Data Byte 3
T2 Bits 23:16	DB2[7:0]: Data Byte 2

Table 677. Tx Buffer Element descriptions (continued)

T2 Bits 15:8	DB1[7:0]: Data Byte 1

T3 Bits 31:24	DB7[7:0]: Data Byte 7
T3 Bits 23:16	DB6[7:0]: Data Byte 6
T3 Bits 15:8	DB5[7:0]: Data Byte 5
RT3 Bits 7:0	DB4[7:0]: Data Byte 4

46.3.6.3 Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

Figure 588. Tx Event FIFO Element

Table 678. Tx Event FIFO Element

E0 Bit 31 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 Bit 30 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 Bit 29 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 Bits 28:0 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 Bits 31:24 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status

Table 678. Tx Event FIFO Element (continued)

E1 Bit 23:22 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 Bit 21 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 Bit 20 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching
E1 Bits 19:16 DLC[3:0]	Data Length Code 0-8 Frame with 0-8 data bytes transmitted 9-15 Frame with 8 data bytes transmitted
E1 Bits 15:0 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

46.3.6.4 Standard message ID filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0 to 127).

	31		24	23		16	15		8	7		0
S0	SFT[1:0]	SFEC[2:0]	SFID1[10:0]			res			SFID2[10:0]			

Figure 589. Standard Message ID Filter Element

Table 679. Standard Message ID Filter Element Field Description

Bits 31:30 SFT[1:0]	Standard Filter Type 00 Range filter from SF1ID to SF2ID ($SF2ID \geq SF1ID$) 01 Dual ID filter for SF1ID or SF2ID 10 Classic filter: SF1ID = filter, SF2ID = mask 11 Reserved
Bit 29:27 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = "100", "101", or "110" a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of SFT[1:0] ignored
Bits 26:16 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 10:0 SFID2[10:0]	Standard Filter ID 2 This bit field has a different meaning depending on the configuration of SFEC: 1) SFEC = "001"... "110" Second ID of standard ID filter element 2) SFEC = "111" Filter for Rx Buffers or for debug messages SFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C SFID2[8:6] is used to control the filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one M_CAN host clock period in case the filter matches. SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

Note: In case a reserved value is configured, the filter element is considered disabled.

46.3.6.5 Extended message ID filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address $XIDFC[FLESA]$ plus two times the index of the filter element (0...63).

Figure 590. Extended Message ID Filter Element

Table 680. Extended Message ID Filter Element Field Description

F0 Bits 31:29 EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = "100", "101", or "110" a match sets interrupt flag IR[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored
F0 Bits 28:0 EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see Section 46.3.6.5, Extended message ID filter element) is used.

Table 680. Extended Message ID Filter Element Field Description (continued)

F1 Bits 31:30 EFT[1:0]	Extended Filter Type 00 Range filter from EF1ID to EF2ID ($EF2ID \geq EF1ID$) 01 Dual ID filter for EF1ID or EF2ID 10 Classic filter: EF1ID = filter, EF2ID = mask 11 Range filter from EF1ID to EF2ID ($EF2ID \geq EF1ID$), XIDAM mask not applied
F1 Bits 28:0 EFID2[28:0]	This bit field has a different meaning depending on the configuration of EFEC: 1) EFEC = "001"... "110" Second ID of extended ID filter element 2) EFEC = "111" Filter for Rx Buffers or for debug messages EFID2[10:9] decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 00 Store message into an Rx Buffer 01 Debug Message A 10 Debug Message B 11 Debug Message C EFID2[8:6] is used to control the filter event pins m_can_fe[2:0] at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one m_can_hclk period in case the filter matches. EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.

Note: In case a reserved value is configured, the filter element is considered disabled.

46.3.7 M_CAN functional description

46.3.7.1 Operating modes

46.3.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus transmit output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = '1'. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS—High Priority Message Status
- RXF0S—Rx FIFO 0 Status
- RXF1S—Rx FIFO 1 Status
- TXFQS—Tx FIFO/Queue Status
- TXBRP—Tx Buffer Request Pending
- TXBTO—Tx Buffer Transmission Occurred
- TXBCF—Tx Buffer Cancellation Finished
- TXEFS—Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOC] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = '1'.

The following registers are only writable while CCCR[CCE] = '0'

- TXBAR - Tx Buffer Add Request
- TXBCR - Tx Buffer Cancellation Request

CCCR[TEST] and CCCR.MON can only be set by the Host while CCCR[INIT] = '1' and CCCR[CCE] = '1'. Both bits may be reset at any time. CCCR.DAR can only be set/reset while CCCR[INIT] = '1' and CCCR[CCE] = '1'.

Following sequence can be used as an example code for initializing the CAN module (M_CAN0 in example):

```
-- Setting the INIT bit high to start the initialization
    while (read_data != 0x003){
        write(M_CAN0, 0xF, driver.regs.can0_cccr.addr, 0x003);
        read_data = read(M_CAN0, 0xF, driver.regs.can0_cccr.addr);
    };

-- Configuring the time stamp and timeout registers
    write(M_CAN0, 0xF, driver.regs.can0_tscc.addr, 0x000);
    write(M_CAN0, 0xF, driver.regs.can0_tocc.addr, 0x000);

-- Configuring the interrupt registers
    write(M_CAN0, 0xF, driver.regs.can0_ie.addr, 0xFFFFFFFF);
    write(M_CAN0, 0xF, driver.regs.can0_ils.addr, 0x00000002);
    write(M_CAN0, 0xF, driver.regs.can0_ile.addr, 0x00000003);

    write(M_CAN0, 0xF, driver.regs.can0_gfc.addr, 0x000);
    write(M_CAN0, 0xF, driver.regs.can0_xidam.addr, 0x00FFFFFF);

--Writing the start addresses of all the M_CAN Buffers
    generate and drive M_CAN0 can0_rxf0c keeping {
                                                .f0sa == 0x100;
                                                .f0s  == 0x03;
```

```

46.3.7.2 Normal operation

Once the M_CAN is initialized and CCCR[INIT] is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

46.3.7.3 CAN FD Operation

There are two stages in the CAN FD protocol, first the Long Frame Mode where the data field of a CAN frame may be longer than 8 bytes. The second stage is the Fast Frame Mode where control field, data field, and CRC field of a CAN Frame are transmitted with a higher bit rate than the beginning and the end of the frame. Fast Frame Mode can only be used in combination with Long Frame Mode.

The CAN operation mode is chosen by programming CCCR.CME. In case CCCR.CME = g01h transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CCCR.CME = g10h/g11h transmission and reception of long and fast CAN FD frames is enabled. CCCR.CME can only be changed while CCCR.INIT and CCCR.CCE are both set.

When initialization is left (CCCR.INIT set to e0f), both Long Frame Mode and Fast Frame Mode are inactive, they have to be requested by writing to CCCR.CMR. A mode change requested by writing to CCCR.CMR will be executed next time the CAN protocol controller FSM reaches idle phase between CAN frames. Upon this event CCCR.CMR is reset to g00h and the status flags CCCR.FACT and CCCR.LACT are set accordingly. In case the requested CAN operation mode is not enabled, the value written to CCCR.CMR is retained until it is overwritten by the next mode change request. Default is normal CAN operation. A change of the CAN operation mode should not be requested while there are pending transmission requests.

When CCCR.CME = g00h, received frames are interpreted according to the CAN FD Protocol Specification. The reserved bit in CAN frames with 11-bit identifiers and the first reserved bit in CAN frames with 29-bit identifiers will be decoded as EDL bit. EDL = recessive signifies a CAN FD long frame, EDL = dominant signifies a standard CAN frame. In a CAN FD long frame, the two bits following EDL, r0 and BRS, decide whether this CAN FD long frame is also a CAN FD fast frame. A CAN FD fast frame is signified by r0 = dominant and BRS = recessive. The coding of r0 = recessive is reserved for future expansion of the protocol.

The status bits CCCR.LACT and CCCR.FACT indicate the format of transmitted frames. When CCCR.LACT is set, frames will be transmitted in CAN FD long format with EDL = recessive. When both CCCR.LACT and CCCR.FACT are set, frames will be transmitted in CAN FD Fast format with both EDL and BRS = recessive.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the following table.

Table 681. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD fast frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Bit Timing and Prescaler Register BTP. In the following CAN FD data phase, the fast CAN bit timing is used as defined by the

Fast Bit Timing and Prescaler The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant, independent of the transmitter's error state. The data length code of CAN FD remote frames is transmitted as zero.

In case a M_CAN Tx Buffer is configured for CAN FD transmission with DLC > 8, the first 8 bytes are transmitted as configured in the Tx Buffer while the remaining part of the data field is padded with 0xCC. When the M_CAN receives a CAN FD frame with DLC > 8, the first 8 bytes of that frame are stored into the matching Rx Buffer or Rx FIFO. The remaining bytes are discarded.

46.3.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin m_can_tx the protocol controller receives the transmitted data from its local CAN transceiver via pin m_can_rx. The received data is delayed by the CAN transceiver's loop delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transceivers loop delay.

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. [Figure 591](#) below describes how the transceiver loop delay is measured.

Figure 591. Transceiver delay measurement

Within each CAN FD frame, the transmitter measures the delay between the data transmitted at pin m_can_tx and the data received at pin m_can_rx, starting with the falling edge of bit EDL. The delay is measured in m_can_cclk periods.

A secondary sample point is calculated by adding a configurable transceiver delay compensation offset (FBTP.TDCO) to the measured transceiver delay. The transceiver delay compensation offset is used to adjust the secondary sample point inside the bit time (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of time quanta tq.

To check for bit errors during the data phase, the delayed transmit data is compared against the received data at the secondary sample point. If a bit error is detected at the secondary sample point, the transmitter will react to this bit error at the next following sample point. During arbitration phase the delay compensation is always disabled.

The maximum delay which can be compensated by the M_CAN's delay compensation during the data phase is three bit times.

46.3.7.4.1 Configuration and status

Compensation for the transceiver loop delay by the M_CAN is enabled via FBTP.TDC. The transceiver delay compensation offset is configured via FBTP.TDCO. The actual delay compensation value applied by the M_CAN's protocol engine can be read from TEST.TDCV.

46.3.7.5 Bus monitoring mode

The M_CAN is set in Bus Monitoring Mode by programming CCCR[MON] to one. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state. The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits.

[Figure 592](#) shows the connection of M_CAN Tx and Rx signals to the M_CAN in Bus Monitoring Mode.

Figure 592. Pin control in Bus Monitoring mode

46.3.7.6 Disabled automatic retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

46.3.7.6.1 Frame transmission in DAR mode

In DAR mode, all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = "10" (transmission in spite of cancellation).

46.3.7.7 Power down (Sleep mode)

The M_CAN can be set into power down mode controlled by input signal clock stop request or via CC Control Register CCCR[CSR]. As long as the clock stop request signal is active, bit CCCR[CSR] is read as one. When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module clock inputs (CAN clock and host clock) may be switched off. To leave power down mode, the application has to turn on the module clocks before resetting signal clock stop request signal resp. CC Control Register flag CCCR[CSR]. The M_CAN will acknowledge this by resetting clock stop acknowledge output signal and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

46.3.7.8 Test modes

To enable write access to register TEST (see [Section 46.3.5.2.4, Test Register](#)), bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin m_can_tx by programming TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN's bit timing and it can drive constant dominant or

recessive values. The actual value at M_CAN Rx pin can be read from TEST[RX]. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output Tx pin. This applies also when reading input Rx pin via TEST[RX].

Note: Test modes should be used for production tests or self test only. The software control for Tx pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

46.3.7.8.1 External Loop Back mode

The M_CAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. [Figure 593](#) shows the connection of Tx and Rx signals to the M_CAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loop Back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CAN Rx input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the M_CAN Tx pin.

Figure 593. External Loop Back mode

46.3.7.8.2 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a “Hot Selftest”, meaning the M_CAN can be tested without affecting a running CAN system connected to the M_CAN Tx and Rx pins. In this mode M_CAN Tx pin is disconnected from the M_CAN and M_CAN Tx pin is held recessive. [Figure 594](#) shows the connection of M_CAN Tx pin and Rx to the M_CAN in case of Internal Loop Back mode.

Figure 594. Internal loop back mode

46.3.8 Timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1...16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

46.3.9 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC.TCP as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = '0'. It is stopped when CCCR[INIT] = '1', e.g. when the M_CAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC.TOP and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: *The clock signal for the Timeout Counter is derived from the CAN core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.*

46.3.10 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

46.3.10.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
 - Range filter (from - to)
 - Filter for one or two dedicated IDs
 - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Note: When an accepted message is written to one of the two Rx FIFOs, or into a Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

46.3.10.1.1 Range filter

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID. There are two possibilities when range filtering is used together with extended frames:

- EFT = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = "11": The Extended ID AND Mask (XIDAM) is not used for range filtering

46.3.10.1.2 Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID resp. EF1ID = EF2ID.

46.3.10.1.3 Filter for dedicated IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID resp. EF1ID = EF2ID.

46.3.10.1.4 Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering. In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

46.3.10.1.5 Standard message ID filtering

[Figure 589](#) shows the flow for standard message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in [Section 46.4.6.4, Standard message ID Filter element](#).

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 595. Standard Message ID Filter Path

46.3.10.1.6 Extended message ID filtering

[Figure 596](#) below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in [Section 46.3.5.2.20, Extended ID Filter Configuration Register \(XIDFC\)](#).

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 596. Extended Message ID Filter Path

46.3.10.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C. Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see [Section 46.3.10.1, Acceptance filtering](#). The Rx FIFO element is described in [Section 46.3.6.1, Rx Buffer and FIFO element](#).

When an Rx FIFO full condition is signaled by IR[RFnF], no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. In case a message is received while the corresponding

Rx FIFO is full, this message is discarded and interrupt flag IR.RFnL is set. To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC[FnWM], interrupt flag IR[RFnW] is set. When reading from an Rx FIFO, four times the Rx FIFO Get Index RXFnS[FnGI] has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

46.3.11 Dedicated Rx Buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = "111" and SFID2 / EFID2[10:9] = "00" has to be configured (see [Section 46.3.6.4, "Standard message ID filter element"](#) and [Section 46.3.6.5, "Extended message ID filter element"](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 682. Example Filter Configuration for Rx buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message 1	00	00 0000
1	ID debug message 2	00	00 0001
2	ID debug message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

46.3.11.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

46.3.12 Debug on CAN Support

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (e.g. #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element (see [Section 46.3.6.1, "Rx Buffer and FIFO element"](#)).

Advantage: Fixed start address for the DMA transfers (relative to RXBC.RBSA), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = “111” have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output m_can_dma_req is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M_CAN while m_can_dma_req is activated. The behavior is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets m_can_dma_ack. This resets m_can_dma_req. Now the M_CAN is prepared to receive the next set of debug messages.

46.3.12.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to “111”. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR.DRX are set. The reception of debug messages can be monitored via RXF1S.DMS.

Table 683. Example Filter Configuration for debug messages

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

46.3.12.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S.DMS.

Figure 597. Debug Message Handling State Machine

- T0: reset m_cam_dma_req output, enable reception of debug messages A, B, and C
- T1: reception of debug message A
- T2: reception of debug message A
- T3: reception of debug message C
- T4: reception of debug message B
- T5: reception of debug messages A, B
- T6: reception of debug message C
- T7: DMA transfer completed
- T8: reception of debug message A,B,C (message rejected)

46.3.13 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in [Section 46.3.6.2, Tx buffer element](#).

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

46.3.13.1 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional

Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding four times the transmit buffer index (0...31) to the Tx Buffer Start Address TXBC[TBSA].

46.3.13.2 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = '1') is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFOs Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level. When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding four times the Put Index TXFQS[TFQPI] (0...31) to the Tx Buffer Start Address TXBC[TBSA].

46.3.13.3 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding four times the Tx Queue Put Index $\text{TXFQS}[\text{TFQPI}]$ (0...31) to the Tx Buffer Start Address $\text{TXBC}[\text{TBSA}]$.

46.3.13.4 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by $\text{TXBC}[\text{NDTB}]$. The number of Tx Buffers assigned to the Tx FIFO is configured by $\text{TXBC}[\text{TFQS}]$. In case $\text{TXBC}[\text{TFQS}]$ is programmed to zero, only Dedicated Tx Buffers are used.

Figure 598. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by $\text{TXFS}[\text{TFGI}]$)
- Buffer with lowest Message ID gets highest priority and is transmitted next

46.3.13.5 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by $\text{TXBC}[\text{NDTB}]$. The number of Tx Queue Buffers is configured by $\text{TXBC}[\text{TFQS}]$. In case $\text{TXBC}[\text{TFQS}]$ is programmed to zero, only Dedicated Tx Buffers are used.

Figure 599. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

46.3.13.6 Transmit cancellation

The M_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register TXBCF to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

46.3.13.7 Tx Event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in [Section 46.3.6.3, Tx event FIFO element](#). When a Tx Event FIFO full condition is signaled by IR.TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

46.3.14 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see [Section 46.3.5.2.27, Rx FIFO 0 Acknowledge Register \(RXF0A\)](#), [Section 46.3.5.2.31, Rx FIFO 1 Acknowledge Register \(RXF1A\)](#), and [Section 46.3.5.2.43, Tx Event FIFO Acknowledge Register \(TXEFA\)](#)). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFOs Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFOs Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFOs Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

46.3.15 Interface to DMA Controller

When all three debug messages A, B, C have been received in the correct order, M_CAN DMA request signal is activated to trigger a DMA transfer. The RAM words holding debug messages A, B, C will not be changed by the M_CAN while M_CAN DMA request signal is active.

After the transfer of the received messages has completed the DMA unit activates the M_CAN DMA ACK signal. This resets M_CAN DMA request signal. The debug message handling state machine enters idle state (DMS = "00") and waits for reception of the next debug messages.

Figure 600. Timing of DMA interface signals

Note: If the DMA unit activates input M_CAN DMA acknowledge signal before the DMA transfer has completed, the Rx Buffer elements holding debug messages A, B, C are unlocked and may be overwritten by received debug messages.

46.4 Time Triggered Modular CAN (M_TTCAN) core

The M_TTCAN module is the new M_TTCAN Communication Controller IP-module that can be integrated as stand-alone device or as part of an ASIC. The M_TTCAN provides all features of time-triggered communication specified in ISO 11898-4, including event synchronized time-triggered communication, global system time, and clock drift compensation.

In addition the M_TTCAN supports communication according to CAN FD protocol specification 1.0 with data fields of up to eight bytes length. The CAN FD option can be used together with event-triggered and time-triggered CAN communication.

The message storage is intended to be a single-ported Message RAM outside of the module. It is connected to the M_TTCAN via the Generic Master Interface. All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN core as well as providing transmit status information. It implements all functions concerning the time schedule and the global system time.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M_TTCAN's clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FMPLL.

46.4.1 Features

The following are the features of M_TTCAN:

- M_TTCAN protocol level 1 and level 2 completely in hardware
- AUTOSAR optimized
- SAE J1939 optimized
- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1, -4
- CAN FD with max. 8 data bytes supported
- Event synchronized time-triggered communication supported
- CAN Error Logging
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signaling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 Transmit Buffers
- Configurable Transmit FIFO / Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M_(TT)CAN share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 32 bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support

46.4.2 Block Diagram

Figure 601. M_TTCAN core block diagram

- CAN core: CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- Sync: Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- Cfg and Ctrl: CAN core related configuration and control bits.
- Interrupt and Timestamp: Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- Tx Handler: Controls the message transfer from the external Message RAM to the CAN core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported. The Tx Handler also implements the Frame Synchronization Entity FSE which controls time-triggered communication according to ISO11898-4. It synchronizes itself to the reference messages on the CAN bus, controls cycle time and global time, and handles transmissions according to the

predefined message schedule, the system matrix. It also handles the time marks of the system matrix that are linked to the messages in the Message RAM. Stop Watch Trigger, Event Trigger, and Time Mark Interrupt are synchronization interfaces.

- **Rx Handler:** Controls the transfer of received messages from the CAN core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs
- **Clk:** Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- **Generic Slave Interface:** Connects the M_TTCAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8-/16-/32-bit bus to support a wide range of interconnection structures.
- **Generic Master Interface:** Connects the M_TTCAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32 bit.

46.4.3 Dual clock sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN core, a separate clock without any modulation has to be provided as M_TTCAN clock. The CAN core should be programmed to have at least 8 clocks per bit time, this is e.g. 1 Mbaud at M_TTCAN clock ≥ 8 MHz. Even in case of a very high Host clock frequency, the clock frequency of the CAN core needs not to be higher than 8 MHz.

Within the M_TTCAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

Note: *In order to achieve a stable function of the M_TTCAN, the Host clock must always be faster than or equal to the CAN clock. Also the modulation depth of the spread spectrum clock has to be regarded.*

Caution: It is strongly recommended to stop this module when the device is in the STOP mode or in case, if the CAN message reception is mandatory, please check if the PLL is unlocked before transmitting any message, or use the external oscillator instead of the the IRC during the STOP mode.

46.4.4 Dual interrupt lines

The module provides two interrupt lines. Interrupts can be routed either to M_TTCAN INT 0 or to M_TTCAN INT 1. By default all interrupts are routed to interrupt line M_TTCAN INT 0. By programming INT 0 and INT 1 bits of the Interrupt Line Enable (ILE) register, the interrupt lines can be enabled or disabled separately.

46.4.5 Memory map and registers description

46.4.5.1 Hardware reset description

After hardware reset, the registers of the M_TTCAN hold the reset values listed in [Table 684](#). Additionally the Bus_Off state is reset and the CAN transmit output is set to recessive (HIGH). The value 0x0001 (CCCR[INIT] = '1') in the CC Control Register enables

software initialization. The M_TTCAN does not influence the CAN bus until the CPU resets CCCR[INIT] to '0'.

46.4.5.2 Register map

The M_TTCAN module allocates an address space of 512 bytes. All registers are organized as 32-bit registers. The M_TTCAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8-bit (byte access), 16-bit (half-word access), or 32-bit (word access).

Note: Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only with CCCR[CCE]= '1' AND CCCR[INIT]= '1'. There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

46.4.5.2.3 Fast Bit Timing and Prescaler Register (FBTP)

This register is only writable if bits **CCCR.CCE** and **CCCR.INIT** are set. The CAN bit time may be programed in the range of 4 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to 1024 M_TTCAN clock periods. $tq = (FBRP + 1) M_TTCAN$ clock period.

FTSEG1 is the sum of Prop_Seg and Phase_Seg1. **FTSEG2** is Phase_Seg2.

Therefore the length of the bit time is (prog rammed values) **[FTSEG1 + FTSEG2 + 3]** tq or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Figure 604. Fast Bit Timing and Prescaler Register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 687. Fast Bit Timing and Prescaler Register

Field	Description
0:3 TDCO	Transceiver Delay Compensation Offset (0x0–0xF)— Offset value defining the distance between the measured delay from M_TTCAN transmit to M_TTCAN receive and the secondary sample point. Valid values are 0 to 15 M_TTCAN clock periods.
4 TDC	Transceiver Delay Compensation 0 Transceiver Delay Compensation disabled 1 Transceiver Delay Compensation enabled
6:15 FBRP	Fast Baud Rate Prescaler (0x000–0x3FF)— The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
20:23 FTSEG1	Fast time segment before sample point (0x1–0xF) Valid values are 1 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
25:27 FTSEG2	Fast time segment before sample point (0x0–0x7) Valid values are 0 to 7. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
30:31 FSJW	Fast (Re) Synchronization Jump Width (0x0–0x3) Valid values are 0 to 3. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note: With a M_TTCAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_TTCAN for a fast bit rate of 500 kbit/s.

46.4.5.2.4 Test Register (TEST)

Write access to the Test Register has to be enabled by setting bit CCCR[TEST] to '1'. All Test Register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back mode and software control of Tx pin are hardware test modes. Programming of TX ≠ "00" may disturb the message transfer on the CAN bus.

46.4.5.2.5 RAM Watchdog Register (RWD)

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by the **RWD[WDC]** bits. The counter is reloaded with **RWD[WDC]** bits when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag **IR[WDI]** bit is set. The RAM Watchdog Counter is clocked by the Host clock.

20:21 CMR	CAN Mode Request A change of the CAN operation mode is requested by writing to this bit field. After change to the requested operation mode the bit field is reset to "00" and the status flags FACT and LACT are set accordingly. In case the requested CAN operation mode is not enabled, the value written to CMR is retained until it is overwritten by the next mode change request. Default is normal CAN operation. 00 unchanged 01 Long Frame Mode request 10 Long + Fast Frame Mode request 11 Normal CAN operation request
22:23 CME	CAN Mode Enable 00 Normal CAN operation according to ISO11898-1 01 Long Frame Mode enabled 10 Long + Fast Frame Mode enabled 11 Long + Fast Frame Mode enabled <i>Note: In case CME = "01" transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CME = "10"/"11" transmission and reception of long and fast CAN FD frames is enabled.</i>
24 TEST	Test Mode Enable 0 Normal operation, register TEST holds reset values 1 Test Mode, write access to register TEST enabled
25 DAR	DAR: Disable Automatic Retransmission 0 Automatic retransmission of messages not transmitted successfully enabled 1 Automatic retransmission disabled
26 MON	Bus Monitoring Mode Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. 0 Bus Monitoring Mode is disabled 1 Bus Monitoring Mode is enabled
27 CSR	Clock Stop Request 0 No clock stop is requested 1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
28 CSA	Clock Stop Acknowledge 0 No clock stop acknowledged 1 M_TTCAN may be set in power down by stopping host clock and core clock

Table 690. CC Control Register Field Descriptions

Field	Description
29 ASM	ASM Restricted Operation Mode The Restricted Operation Mode is intended for applications that adapt themselves to different CAN bit rates. The application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame. In the optional Restricted Operation Mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. If the M_CAN is connected to a Clock Calibration on CAN unit, ASM is controlled by input M_CAN calibration OK (m_can_cok) signal. In case "m_can_cok" switches to '0', bit ASM is set. When "m_can_cok" switches back to '1', bit ASM returns to the previously written value. The state of ASM is the written value while input "m_can_cok" is at '1'. The input is hardwired to '1' when there is no Clock Calibration on CAN unit connected. 0 Normal CAN operation 1 Restricted Operation Mode active
30 CCE	Configuration Change Enable 0 The CPU has no write access to the protected configuration registers 1 The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
31 INIT	Initialization 0 Normal Operation 1 Initialization is started

Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

46.4.5.2.7 Bit Timing and Prescaler Register (BTP)

This register is only writable if bits **CCCR[CCE]** and **CCCR[INIT]** are set. The CAN bit time may be programmed in the range of [4...25] time quanta (tq). The CAN time quantum may be programmed in the range of [1...1024] M_TTCAN core clockperiods.

$$\text{Equation 28} \quad tq = (BRP + 1) M_TTCAN \text{ clock period}$$

where $BRP = (0x40 \cdot BRPE) + BRPL$.

TSEG1 is the sum of Prop_Seg and Phase_Seg1. **TSEG2** is Phase_Seg2. Therefore the length of the bit time is (programmed values) $[TSEG1 + TSEG2 + 3] tq$ or (functional values) $[Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] tq$.

Figure 608. Bit Timing and Prescaler Register

W																
Reset	0	0	0	0	1	0	1	0	0	0	1	1	0	0	1	1

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 691. Bit Timing and Prescaler Field Descriptions

Field	Description
0:5	Reserved
6:15 BRPE	Baud Rate Prescaler Extension (0x000–0x3FF) The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values for the Baud Rate Prescaler are 0 to 1023. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
16:17	Reserved
18:23 TSEG1	(0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
24:27 TSEG2	(0x0–0xF) Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.
28:31 SJW	(Re) Synchronization Jump Width (0x0–0x3) valid programmed values are 0-3. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used

Note: With a CAN clock of 8 MHz, the reset value of 0x00002301 configures the M_TTCAN for a bit rate of 500 kbit/s.

Note: The Information Processing Time (IPT) of the M_TTCAN is 0 tq. Therefore, to conform to the CAN protocol specification, the lengths for phase segment 1 (Phase_Seg1) and phase segment 2 (Phase_Seg2) must be equal.

46.4.5.2.8 Timestamp Counter Configuration Register (TSCC)

Figure 609. Timestamp Counter Configuration Register

Address: 0x0020

1. These are protected write (P) bits which means that write access by the bit is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 692. Timestamp Counter Configuration Field Descriptions

Field	Description
0:11	Reserved
12:15 TCP	Timestamp Counter Prescaler 0x0–0xF Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1...16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. <i>Note: With CAN FD an external counter is required for timestamp generation (TSS = "10")</i>
16:29	Reserved
30:31 TSS	Timestamp Select 00 Timestamp counter value always 0x0000 01 Timestamp counter value incremented according to TCP 10 Reserved 11 Same as "00"

46.4.5.2.9 Timestamp Counter Value Register (TSCV)

Figure 610. Timestamp counter value register

Table 693. Timestamp counter value field descriptions

Field	Description
0:15	Reserved
16:30 TSC	Timestamp Counter The Timestamp Counter value is captured on start of frame (both Rx and Tx). When TSCC[TSS] = "01", the Timestamp Counter is incremented in multiples of CAN bit times [1...16] depending on the configuration of TSCC[TCP] . A wrap around sets interrupt flag IR[TSW] . Write access resets the counter to zero.

Note: A “wrap around” is a change of the Timestamp Counter value from non-zero to zero not caused by write access to TSCV.

46.4.5.2.10 Timeout Counter Configuration Register (TOCC)

For a description of the Timeout Counter see [Section 46.4.7.11, Timeout counter](#).

Figure 611. Timeout counter configuration register

1. These are protected write (P) bits which means that write access by the bit is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 694. Timeout counter configuration field descriptions

Field	Description
0:15 TOP[15:0]	Timeout Period Start value of the Timeout Counter (down-counter). Configures the Timeout Period.
16:28	Reserved
29:30 TOS	Timeout Select When operating in Continuous mode, a write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting. When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP] . Down-counting is started when the first FIFO element is stored. 00 Continuous operation 01 Timeout controlled by Tx Event FIFO 10 Timeout controlled by Rx FIFO 0 11 Timeout controlled by Rx FIFO 1
31 ETOC	Enable Timeout Counter 0 Timeout Counter disabled 1 Timeout Counter enabled <i>Note: For use of timeout function with CAN FD see Section 46.4.7.11, "Timeout counter".</i>

2. Access type is RS: set on read.

Table 697. PSR descriptions

Field	Description
0:17	Reserved

Table 697. PSR descriptions (continued)

Field	Description
18 REDL	Received CAN FD Message 0 Since this bit was reset by the CPU, no CAN FD message has been received 1 Message in CAN FD format with EDL flag set has been received
19 RBRS	BRS flag of last received CAN FD Message This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not have its BRS flag set. 1 Last received CAN FD message had its BRS flag set.
20 RESI	ESI CAN FD Message with ESI flag This bit is set together with REDL, independent of acceptance filtering. 0 Last received CAN FD message did not have its ESI flag set. 1 Last received CAN FD message had its ESI flag set
21 FLEC	Fast Last Error Code Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.
24 BO	Bus_Off Status 0 The M_TTCAN is not Bus_Off 1 The M_TTCAN is in Bus_Off state
25 EW	Warning Status 0 Both error counters are below the Error_Warning limit of 96 1 At least one of error counter has reached the Error_Warning limit of 96
26 EP	Error Passive 0 The M_TTCAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1 The M_TTCAN is in the Error_Passive state
27:28 ACT	Activity Monitors the module's CAN communication state. 00 Synchronizing — node is synchronizing on CAN communication 01 Idle — node is neither receiver nor transmitter 10 Receiver — node is operating as receiver 11 Transmitter — node is operating as transmitter

Table 697. PSR descriptions (continued)

Field	Description
29:31 LEC	Last Error Code The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 000 No Error: No error occurred since LEC has been reset by successful reception or transmission. 001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010 Form Error: A fixed format part of a received frame has the wrong format. 011 AckError: The message transmitted by the M_TTCAN was not acknowledged by another node. 100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110 CRCErrror: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Note: When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error

Note: The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT]. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR[INIT] has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129×11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR[INIT], each time a sequence of 11 recessive bits has been monitored, a Bit0 Error code is written to PSR[LEC], enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR[REC] is used to count these sequences.

46.4.5.2.14 Interrupt Register (IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register. The configuration of **IE** controls whether an interrupt is generated. The configuration of **ILS** controls on which interrupt line an interrupt is signaled.

46.4.5.2.16 Interrupt Line Select Register (ILS)

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE[EINT0] and ILE[EINT1].

Figure 617. Interrupt line select register

46.4.5.2.17 Interrupt Line Enable Register (ILE)

Each of the two interrupt lines to the CPU can be enabled / disabled separately by programming bits **EINT0** and **EINT1**.

Figure 618. Interrupt line enable register

Table 701. Interrupt line enable register field descriptions

Field	Description
0:29	Reserved
30 EINT1	Enable Interrupt Line 1 0 Interrupt line disabled 1 Interrupt line enabled
31 EINT0	Enable Interrupt Line 0 0 Interrupt line disabled 1 Interrupt line enabled

46.4.5.2.18 Global Filter Configuration Register (GFC)

Global settings for Message ID filtering. The Global Filter Configuration controls the filter path for standard and extended messages as described in [Figure 674](#) and [Figure 675](#).

Figure 619. Global filter configuration register

Address: 0x0080														Access: RP			
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 702. Global filter configuration register field descriptions

Field	Description
0:25	Reserved
26:27 ANFS	Accept Non-matching Frames Standard Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated. 00 Accept in Rx FIFO 0 01 Accept in Rx FIFO 1 10 Reject 11 Reject
28:29 ANFE	Accept Non-matching Frames Extended Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated. 00 Accept in Rx FIFO 0 01 Accept in Rx FIFO 1 10 Reject 11 Reject
30 RRFS	Reject Remote Frames Standard 0 Filter remote frames with 11-bit standard IDs 1 Reject all remote frames with 11-bit standard IDs
31 RRFE	Reject Remote Frames Extended 0 Filter remote frames with 29-bit extended IDs 1 Reject all remote frames with 29-bit extended IDs

46.4.5.2.19 Standard ID Filter Configuration Register (SIDFC)

Settings for 11-bit standard Message ID filtering. The Standard ID Filter Configuration controls the filter path for standard messages as described in [Figure 674](#)

Figure 620. Standard ID Filter Configuration register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 703. Standard ID Filter Configuration register field descriptions

Field	Description
0:7	Reserved
8:15 LSS	List Size Standard 0 No standard Message ID filter 1-128 Number of standard Message ID filter elements >128 Values greater than 128 are interpreted as 128
16:29 FLSSA	Filter List Standard Start Address Start address of standard Message ID filter list (32-bit word address, see Figure 668).
30:31	Reserved

46.4.5.2.20 Extended ID Filter Configuration Register (XIDFC)

Settings for 29-bit extended Message ID filtering. The Extended ID Filter Configuration controls the filter path for standard messages as described in [Figure 675](#)

Figure 621. Extended ID Filter Configuration register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 704. Extended ID Filter Configuration register field descriptions

Field	Description
0:8	Reserved
9:15 LSELS	List Size Extended 0 No extended Message ID filter 1-64 Number of extended Message ID filter elements >64 Values greater than 64 are interpreted as 64
16:29 FLESA	Filter List Extended Start Address Start address of extended Message ID filter list (32-bit word address, see Figure 669).
30:31	Reserved

46.4.5.2.21 Extended ID and Mask Register (XIDAM)

Figure 622. Extended ID and Mask register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 705. Extended ID and Mask register field descriptions

Field	Description
0:2	Reserved
3:31 EIDM	Extended ID Mask For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active

46.4.5.2.22 High Priority Message Status Register (HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event match. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Figure 623. High Priority Message Status register

Table 706. High Priority Message Status register field descriptions

Field	Description
0:15	Reserved
16 FLST	Filter List Indicates the filter list of the matching filter element. 0 Standard Filter List 1 Extended Filter List
17:23 FIDX	Filter Index Index of matching filter element. Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
24:25 MSI	Message Storage Indicator 00 No FIFO selected 01 FIFO overrun 10 Message stored in FIFO 0 11 Message stored in FIFO 1
26:31 BIDX	Buffer Index Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = '1'.

46.4.5.2.23 New Data 1 Register (NDAT1)

Figure 624. NDAT1 register

Address: 0x0098

Table 714. Tx Buffer Configuration register field description

Field	Description
0	Reserved
1 TFQM	Tx FIFO/Queue Mode. 0 Tx FIFO operation 1 Tx Queue operation
[2:7] TFQS	Transmit FIFO/Queue Size. 0 No Tx FIFO/Queue 1-32 Number of Tx Buffers used for Tx FIFO/Queue >32 Values greater than 32 are interpreted as 32
[8:9]	Reserved
[10:15] NDTB	Number of Dedicated Transmit Buffers. 0 No Dedicated Tx Buffers 1-32 Number of Dedicated Tx Buffers >32 Values greater than 32 are interpreted as 32
[16:29] TBSA	Tx Buffers Start Address. Start address of Tx Buffers section in Message RAM (32-bit word address, Figure 664).
[30:31]	Reserved

Note: Be aware that the sum of TFQS and NDTB may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.

46.4.5.2.33 Tx FIFO/Queue Status Register (TXFQS)

The Tx FIFO/Queue status is related to the pending Tx requests listed in register **TXBRP**. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (**TXBRP** not yet updated).

Figure 636. Tx FIFO/Queue Status register

Table 715. Tx FIFO/Queue Status register field description

Field	Description
[0:9]	Reserved
10 TFQF	Tx FIFO/Queue Full 0 Tx FIFO/Queue not full 1 Tx FIFO/Queue full
[11:15] TFQPI	Tx FIFO/Queue Put Index Tx FIFO/Queue write index pointer, range 0 to 31
[16:18]	Reserved
[19:23] TFGI	Tx FIFO Get Index. Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx Queue operation is configured (TXBC.TFQM = '1')
[24:25]	Reserved
[26:31] TFFL	Tx FIFO Free Level Number of consecutive free Tx FIFO elements starting from TFGI , range 0 to 32. Read as zero when Tx Queue operation is configured (TXBC[TFQM] = '1')

Note: In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Index indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

For example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

46.4.5.2.34 Tx Buffer Request Pending Register (TXBRP)

Table 716. Tx Buffer Request Pending register field description

Field	Description
[0:31] TRP	Transmission Request Pending. Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR. TXBRP bits are set only for those Tx Buffers configured via TXBC. After a TXBRP bit has been set, a Tx scan (see Section 46.4.7.15, Tx handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID). A cancellation request resets the corresponding transmission request pending bit of register TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset. After a cancellation has been requested, a finished cancellation is signaled via TXBCF • after successful transmission together with the corresponding TXBTO bit • when the transmission has not yet been started at the point of cancellation • when the transmission has been aborted due to lost arbitration • when an error occurred during frame transmission In DAR mode all transmissions are automatically cancelled if they are not successful. The corresponding TXBCF bit is set for all unsuccessful transmissions. 0 No transmission request pending 1 Transmission request pending

Note: *TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.*

46.4.5.2.35 Tx Buffer Add Request Register (TXBAR)

Table 717. Tx Buffer and Request register field description

Field	Description
[0:31] AR	Add Request. Each Tx Buffer has its own Add Request bit. Writing a '1' will set the corresponding Add Request bit; writing a '0' has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to TXBAR. TXBAR bits are set only for those Tx Buffers configured via TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed. 0 No transmission request added 1 Transmission requested added

Note: If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

46.4.5.2.36 Tx Buffer Cancellation Request Register (TXBCR)

Note: ISO 11898-4, Section 5.2.1 requires, that only the listed cycle count values are configured. Other values are possible but may lead to inconsistent matrix cycles.

46.4.5.2.48 TUR Configuration Register (TURCF)

The length of the NTU is given by: $NTU = \text{CAN Clock Period} \times \text{NC/DC}$

NC is an 18-bit value. Its high part, **NCH**[17:16] is hard wired to 0b01. Therefore the range of **NC** is 0x10000...0x1FFFF. The value configured by **NCL** is the initial value for **TURN**A[NAV[15:0]]. **DC** is set to 0x1000 by hardware reset and it may not be written to 0x0000.

Level 1: **NC** $\geq 4 \times \text{DC}$ and $NTU = \text{CAN bit time}$

Level 0, 2: **NC** $\geq 8 \times \text{DC}$

The actual value of TUR may be changed by the clock drift compensation function of M_TTCAN Level 0 and Level 2 in order to adjust the node's local view of the NTU to the time master's view of the NTU. **DC** will not be changed by the automatic drift compensation, **TURN**A[NAV] may be adjusted around **NC** in the range of the Synchronization Deviation Limit given by **TTOCF**[LDSDL]. **NC** and **DC** should be programmed to the largest suitable values in order to allow the best computational accuracy for the drift compensation process.

Figure 651. TUR Configuration register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 730. TUR Configuration register field description

Field	Description
0 ELT	Enable Local Time. 0 Local time is stopped, default 1 Local time is enabled Please note that the local time is started by setting ELT. It remains active until ELT is reset or until the next hardware reset. TURCF[DC] is locked when TURCF[ELT] = '1'. If ELT is written to '0', the readable value will stay at '1' until the new value has been synchronized into the CAN clock domain. During this time write access to the other bits of the register remains locked.
1	Reserved.
[2:15] DC	Denominator Configuration. 0x0000 Illegal value 0x0001–3FFF Denominator Configuration
[16:31] NCL	Numerator Configuration Low. Write access to the TUR Numerator Configuration Low is only possible during configuration with TURCF[ELT] = '0' or if TTOCF[EECS] (external clock synchronization enabled) is set. When a new value for NCL is written outside TT Configuration Mode, the new value takes effect when TTOST.WECS is cleared to '0'. NCL is locked TTOST[WECS] is '1'. 0x0000–FFFF Numerator Configuration Low

Note: If $NC < 7 \times DC$ in *M_TTCAN* Level 1, then it is required that subsequent Time Marks in the Trigger Memory must differ by at least two NTU.

46.4.5.2.49 TT Operation Control Register (TTOCN)

Figure 652. TT Operation Control register

1. These are protected write (P) bits which means that write access by the bits is possible only when the bit 1 [CCE] and bit 0 [INIT] of CCCR register are set to "1".

Table 731. TT Operation Control register field description

Field	Description
[0:15]	Reserved.
16 LCKC	TT Operation Control Register Locked. Set by a write access to register TTOCN. Reset when the updated configuration has been synchronized into the CAN clock domain. 0 Write access to TTOCN enabled 1 Write access to TTOCN locked
17	Reserved.
18 ESCN	External Synchronization Control If enabled the M_TTCAN synchronizes its cycle time phase to an external event signaled by a rising edge at Event Trigger pin(Section 46.4.19, Synchronization to external time schedule). 0 External synchronization disabled 1 External synchronization enabled
19 NIG	Next is Gap. This bit can only be set when the M_TTCAN is the actual Time Master and when it is configured for external event-synchronized time-triggered operation (TTOCF[GEN] = '1') 0 No action, reset by reception of any Reference message 1 Transmit next Reference Message with Next_is_Gap = '1'
20 TMG	Time Mark Gap. 0 Reset by each Reference message 1 Next Reference message started when Register Time Mark interrupt TTIR[RTMI] is activated

Table 731. TT Operation Control register field description

Field	Description
21 FGP	Finish Gap. Set by the CPU, reset by each reference message 0 No reference message requested 1 Application requested start of reference message
22 GCS	Gap Control Select 0 Gap control independent from Event trigger 1 Gap control by input Event trigger pin
23 TTIE	Trigger Time Mark Interrupt Pulse Enable External time mark events are configured by trigger memory element TMEX. A trigger time mark interrupt pulse is generated when the trigger memory element becomes active, and the M_TTCAN is in synchronization state In_Schedule or In_Gap. 0 Trigger Time Mark Interrupt output m_ttcn_tmp disabled 1 Trigger Time Mark Interrupt output m_ttcn_tmp enabled
24:25 TMC	Register Time Mark Compare. 00 No Register Time Mark Interrupt generated 01 Register Time Mark Interrupt if Time Mark = cycle time 10 Register Time Mark Interrupt if Time Mark = local time 11 Register Time Mark Interrupt if Time Mark = global time Please note when changing the time mark reference (cycle, local, global time), it is recommended to first write TMC = "00", then reconfigure TTTMK, and finally set TMC to the intended time reference.
26 RTIE	Register Time Mark Interrupt Pulse Enable. Register time mark interrupts are configured by register TTTMK . A register time mark interrupt pulse with the length of one m_ttcn_clk period is generated when time referenced by TTOCN[TMC] (cycle, local, or global) equals TTTMK[TM] , independent of the synchronization state. 0 Register Time Mark Interrupt output disabled 1 Register Time Mark Interrupt output enabled
[27:28] SWS	Stop Watch Source. 00 Stop Watch disabled 01 Actual value of cycle time is copied to TTCPT[SWV] 10 Actual value of local time is copied to TTCPT[SWV] 11 Actual value of global time is copied to TTCPT[SWV]
29 SWP	Stop Watch Polarity. 0 Rising edge trigger 1 Falling edge trigger
30 ECS	External Clock Synchronization. Writing a '1' to ECS sets TTOST[WECS] if the node is the actual Time Master. ECS is reset after one Host clock period. The external clock synchronization takes effect at the start of the next basic cycle.
31 SGT	Set Global time. Writing a '1' to SGT sets TTOST[WGDT] if the node is the actual Time Master. SGT is reset after one Host clock period. The global time preset takes effect when the node transmits the next Reference message with the Master_Ref_Mark modified by the preset value written to TTGTP .

46.4.5.2.50 TT Global Time Preset Register (TTGTP)

If **TTOST.WGDT** is set, the next Reference message will be transmitted with the **Master_Ref_Mark** modified by the preset value and with **Disc_Bit** = '1', presetting the global time in all nodes simultaneously.

TP is reset to 0x0000 each time a Reference message with **Disc_Bit** = '1' becomes valid or if the node is not the current Time Master. **TP** is locked while **TTOST[WGTD]** = '1' after setting **TTOCN[SGT]** until the Reference message with **Disc_Bit** = '1' becomes valid or until the node is no longer the current Time Master.

Table 733. TT Time Mark register field description

Field	Description
0 LCKM	TT Time Mark Register Locked. Always set by a write access to registers TTOCN. Set by write access to register TTTMK when TTOCN[TMC] ≠ "00". Reset when the registers have been synchronized into the CAN clock domain. 0 Write access to TTTMK enabled 1 Write access to TTTMK locked
1:8	Reserved
[9:15] TICC	Time Mark Cycle Code. Cycle count for which the time mark is valid. 0b000000x valid for all cycles 0b000001c valid every second cycle at cycle count mod2 = c 0b00001cc valid every fourth cycle at cycle count mod4 = cc 0b0001ccc valid every eighth cycle at cycle count mod8 = ccc 0b001cccc valid every sixteenth cycle at cycle count mod16 = cccc 0b01ccccc valid every thirty-second cycle at cycle count mod32 = cccccc 0b1cccccc valid every sixty-fourth cycle at cycle count mod64 = ccccccc
[16:31] TM	Time Mark. 0x0000–FFFF Time Mark

Note: When using byte access to register TTTMK it is recommended to first disable the time mark compare function (**TTOCN[TMC]** = "00") to avoid compares on inconsistent register values.

46.4.5.2.52 TT Interrupt Register (TTIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. A hard reset will clear the register.

46.4.5.2.54 TT Interrupt Line Select Register (TTILS)

The TT Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the TT Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE[EINT0] and ILE[EINT1].

0 TT interrupt assigned to interrupt line 0

1 TT interrupt assigned to interrupt line 1

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Table 737. TT Operation Status register field description

Field	Description
0 SPL	Schedule Phase Lock. The bit is valid only when external synchronization is enabled (TTOCN[ESCN] = '1'). In this case it signals that the difference between cycle time configured by TTGTP[CTP] and the cycle time at the rising edge at event trigger pin is less or equal 9 NTU (see Section 46.4.19, Synchronization to external time schedule). 0 Phase outside range 1 Phase inside range
1 WECS	Wait for External Clock Synchronization. 0 No external clock synchronization pending 1 Node waits for external clock synchronization to take effect. The bit is reset at the start of the next basic cycle.
2 AWE	Application Watchdog Event. The application watchdog is served by reading TTOST. When the watchdog is not served in time, bit AWE is set, all M_TTCAN communication is stopped, and the M_TTCAN is set into Bus Monitoring Mode. 0 Application Watchdog served in time 1 Failed to serve Application Watchdog in time

Table 737. TT Operation Status register field description

Field	Description
3 WFE	Wait for Event. 0 No Gap announced, reset by a Reference Message with Next_is_Gap = '0' 1 Reference Message with Next_is_Gap = '1' received
4 GSI	Gap Started Indicator. 0 No Gap in schedule, reset by each reference message and for all time slaves 1 Gap time after Basic Cycle has started
[5:7] TMP	Time Master Priority. 0x0-7 Priority of actual Time Master
8 GFI	Gap Finished Indicator. Set when the CPU writes TTOCN[FGP] , or by a Time Mark Interrupt if TMG = '1', or via input pin (event trigger) if TTOCN[GCS] = '1'. Not set by Ref_Trigger_Gap or when Gap is finished by another node sending a reference message. 0 Reset at the end of each reference message 1 Gap finished by M_TTCAN
9 WGTD	Wait for Global Time Discontinuity. 0 No global time preset pending 1 Node waits for the global time preset to take effect. The bit is reset when the node has transmitted a Reference message with Disc_Bit = '1' or after it received a Reference message.
[16:23] RTO	Reference Trigger Offset. The Reference Trigger Offset value is a signed integer with a range from -127 (0x81) to 127 (0x7F). There is no notification when the lower limit of -127 is reached. In case the M_TTCAN becomes Time Master (MS[1:0] = "11"), the reset of RTO is delayed due to synchronization between Host and CAN clock domain. For time slaves the value configured by TTOCF[IRTO] is read. 0x00-FF Actual Reference Trigger offset value
24 QCS	Quality of Clock Speed. Only relevant in M_TTCAN Level 0 and Level 2, otherwise fixed to '1'. 0 Local clock speed not synchronized to Time Master clock speed 1 Synchronization Deviation $\leq$ SDL
25 QGTP	Quality of Global Time Phase. Only relevant in M_TTCAN Level 0 and Level 2, otherwise fixed to '0'. 0 Global time not valid 1 Global time in phase with Time Master
[26:27] SYS	Synchronization State. 00 Out of Synchronization 01 Synchronizing to M_TTCAN communication 10 Schedule suspended by Gap (In_Gap) 11 Synchronized to schedule (In_Schedule)

Table 737. TT Operation Status register field description

46.4.5.2.56 TUR Numerator Actual Register (TURNA)

There is no drift compensation in M_TTCAN Level 1 (**NAV = NC**). In M_TTCAN Level 0 and Level 2, the drift between the node's local clock and the time master's local clock is calculated. The drift is compensated when the Synchronization Deviation (difference between **NC** and the calculated **NAV**) is not more than $2^{(TTOCF[LDSDL] + 5)}$. With **TTOCF[LDSDL] ≤ 7**, this results in a maximum range for **NAV** of $(NC - 0x1000) ≤ NAV ≤ (NC + 0x1000)$.

Table 741. TT Capture Time register field description

Field	Description
[0:15] SWV	Stop Watch Value. On a rising/falling edge (as configured via TTOCN[SWP]) at the Stop Watch Trigger pin , when TTOCN[SWS] is $\neq$ "00" and TTIR[SWE] is '0', the actual time value as selected by TTOCN[SWS] (cycle, local, global) is copied to SWV and TTIR[SWE] will be set to '1'. Capturing of the next stop watch value is enabled by resetting TTIR[SWE] . 0x0000–FFFF Captured Stop Watch value
[26:31] CCV	Cycle Count Value. Cycle count value captured together with SWV . 0x00–3F Captured cycle count value

46.4.5.2.60 TT Cycle Sync Mark Register (TTCSM)

Figure 663. TT Cycle Sync Mark register

Table 742. TT Cycle Sync Mark register field description

Field	Description
[0:15]	Reserved.
[16:31] CSM	Cycle Sync Mark. The Cycle Sync Mark is measured in cycle time. It is updated when the reference message becomes valid and retains its value until the next reference message becomes valid. 0x0000–FFFF Captured cycle time

46.4.6 Message RAM

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word. The M_TTCAN module can be configured to allocate up to 1344 words in the Message RAM. It is not necessary to configure each of the sections listed in the following figure, nor is there any restriction with respect to the sequence of the sections.

Figure 664. Message RAM Configuration

When the M_TTCAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configured start addresses are 32-bit word addresses.

Note: The M_TTCAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

46.4.6.1 Rx Buffer and FIFO element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer/ FIFO element is shown below.

Figure 665. Rx Buffer and FIFO Element

Table 743. Rx Buffer and FIFO Element descriptions

R0 Bit 31 ESI: Error State Indicator	0 Transmitting node is error active 1 Transmitting node is error passive
R0 Bit 30 XTD: Extended Identifier	Signals to the Host whether the received frame has a standard or extended identifier. 0 11-bit standard identifier 1 29-bit extended identifier
R0 Bit 29 RTR: Remote Transmission Request	Signals to the Host whether the received frame is a data frame or a remote frame. 0 Received frame is a data frame 1 Received frame is a remote frame
R0 Bits 28:0 ID[28:0]: Identifier	Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
R1 Bit 31 ANMF: Accepted Non-matching Frame	Acceptance of non-matching frames may be enabled via GFC[ANFS] and GFC[ANFE]. 0 Received frame matching filter index FIDX 1 Received frame did not match any Rx filter element
R1 Bits 30:24 FIDX[6:0]: Filter Index	0-127=Index of matching Rx acceptance filter element (invalid if ANMF = '1'). Range is 0 to SIDFC[LSS] - 1 resp. XIDFC[LSE] - 1.
R1 Bit 21 EDL Extended Data Length	0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)

Table 743. Rx Buffer and FIFO Element descriptions (continued)

R1 Bit 20 BRS Bit Rate Switch	0 Frame received without bit rate switching 1 Frame received with bit rate switching
R1 Bits 19:16 DLC[3:0]: Data Length Code	0-8 Received frame has 0-8 data bytes 9-15 Received frame has 8 data bytes
R1 Bits 15:0 RXTS[15:0]: Rx Timestamp	Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].
R2 Bits 31:24	DB3[7:0]: Data Byte 3
R2 Bits 23:16	DB2[7:0]: Data Byte 2
R2 Bits 15:8	DB1[7:0]: Data Byte 1
R2 Bits 7:0	DB0[7:0]: Data Byte 0
R3 Bits 31:24	DB7[7:0]: Data Byte 7
R3 Bits 23:16	DB6[7:0]: Data Byte 6
R3 Bits 15:8	DB5[7:0]: Data Byte 5
R3 Bits 7:0	DB4[7:0]: Data Byte 4

46.4.6.2 Tx Buffer element

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC[TFQS] and TXBC[NDTB].

Figure 666. Tx Buffer Element

T3 Bits 31:24	DB7[7:0]: Data Byte 7
T3 Bits 23:16	DB6[7:0]: Data Byte 6
T3 Bits 15:8	DB5[7:0]: Data Byte 5
RT3 Bits 7:0	DB4[7:0]: Data Byte 4

46.4.6.3 Tx Event FIFO element

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

Figure 667. Tx Event FIFO Element

Table 745. Tx Event FIFO Element

E0 Bit 31 ESI	Error State Indicator 0 Transmitting node is error active 1 Transmitting node is error passive
E0 Bit 30 XTD	Extended Identifier 0 11-bit standard identifier 1 29-bit extended identifier
E0 Bit 29 RTR	Remote Transmission Request 0 Data frame transmitted 1 Remote frame transmitted
E0 Bits 28:0 ID[28:0]	Identifier Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
E1 Bits 31:24 MM[7:0]	Message Marker Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status
E1 Bit 23:22 ET[1:0]	Event Type 00 Reserved 01 Tx event 10 Transmission in spite of cancellation (always set for transmissions in DAR mode) 11 Reserved
E1 Bit 21 EDL	Extended Data Length 0 Standard frame format 1 CAN FD frame format (new DLC-coding and CRC)
E1 Bit 20 BRS	Bit Rate Switch 0 Frame transmitted without bit rate switching 1 Frame transmitted with bit rate switching
E1 Bits 19:16 DLC[3:0]	Data Length Code 0-8 Frame with 0-8 data bytes transmitted 9-15 Frame with 8 data bytes transmitted
E1 Bits 15:0 TXTS[15:0]	Tx Timestamp Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC[TCP].

46.4.6.4 Standard message ID Filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC.FLSSA plus the index of the filter element (0...127).

Figure 668. Standard Message ID Filter Element

Table 746. Standard Message ID Filter Element Field Description

Bits 31:30 SFT[1:0]	Standard Filter Type First ID of standard ID filter element.
Bit 29:27 SFEC[2:0]	Standard Filter Element Configuration All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = "100", "101", or "110" a match sets interrupt flag IE[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer, configuration of SFT[1:0] ignored
Bits 26:16 SFID1[10:0]	Standard Filter ID 1 First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.
Bits 10:0 SFID2[10:0]	Standard Filter ID 2 Second ID of standard ID filter element

Note: In case a reserved value is configured, the filter element is considered disabled.

46.4.6.5 Extended message ID filter element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address $XIDFC[FLESA]$ plus two times the index of the filter element (0...63).

Figure 669. Extended Message ID Filter Element

Table 747. Extended Message ID Filter Element Field Description

F0 Bits 31:29 EFEC[2:0]	Extended Filter Element Configuration All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = "100", "101", or "110" a match sets interrupt flag IE[HPM] and, if enabled, an interrupt is generated. In this case register HPMS is updated with the status of the priority match. 000 Disable filter element 001 Store in Rx FIFO 0 if filter matches 010 Store in Rx FIFO 1 if filter matches 011 Reject ID if filter matches 100 Set priority if filter matches 101 Set priority and store in FIFO 0 if filter matches 110 Set priority and store in FIFO 1 if filter matches 111 Store into Rx Buffer, configuration of EFT[1:0] ignored
F0 Bits 28:0 EFID1[28:0]	Extended Filter ID 1 First ID of extended ID filter element.
F1 Bits 31:30 EFT[1:0]	Extended Filter Type 00 Range filter from EF1ID to EF2ID ($EF2ID \geq EF1ID$) 01 Dual ID filter for EF1ID or EF2ID 10 Classic filter: EF1ID = filter, EF2ID = mask 11 Range filter from EF1ID to EF2ID ($EF2ID \geq EF1ID$), XIDAM mask not applied
F1 Bits 28:0 EFID2[28:0]	Extended Filter ID 2

46.4.6.6 Trigger memory element

Up to 64 trigger memory elements can be configured. When accessing a Trigger Memory element, its address is the Trigger Memory Start Address TTTMC[TMSA] plus the index of the trigger memory element (0...63).

Figure 670. Trigger Memory Element

Table 748. Trigger Memory Element Field Description

T0 Bit 31:16 TM[15:0]	Time Mark Cycle time for which the trigger becomes active.
T0 Bit 14:8 CC[6:0]	Cycle Code Cycle count for which the trigger is valid. Ignored for trigger types Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, End_of_List. 0b000000x valid for all cycles 0b000001c valid every 2nd cycle at cycle count mod2 = c 0b00001cc valid every 4th cycle at cycle count mod4 = cc 0b0001ccc valid every 8th cycle at cycle count mod8 = ccc 0b001cccc valid every 16th cycle at cycle count mod16 = cccc 0b01ccccc valid every 32nd cycle at cycle count mod32 = cccccc 0b1cccccc valid every 64th cycle at cycle count mod64 = ccccccc
T0 Bit 7:6 ASC[1:0]	Time Mark Event Internal 0 No action 1 TTIR.TTMI is set when trigger memory element becomes active
T0 Bit 5 TMIN	Extended Filter ID 2 Second ID of extended ID filter element.

Table 748. Trigger Memory Element Field Description (continued)

T0 Bit 3:0 TYPE[3:0]:	Trigger Type 0000 Tx_Ref_Trigger - valid when not in Gap 0001 Tx_Ref_Trigger_Gap - valid when in Gap 0010 Tx_Trigger_Single - starts a single transmission in an exclusive time window 0011 Tx_Trigger_Continuous - starts continuous transmission in an exclusive time window 0100 Tx_Trigger_Arbitration - starts a transmission in an arbitrating time window 0101 Tx_Trigger_Merged - starts a merged arbitration window 0110 Watch_Trigger - valid when not in Gap 0111 Watch_Trigger_Gap - valid when in Gap 1000 Rx_Trigger - check for reception 1001 Time_Base_Trigger - only control TMIN, TMEX, and ASC 1010...1111=End_of_List - illegal type, causes config error Note: For ASC operation (ASC = "10", "11") only trigger types Rx_Trigger and Time_Base_Trigger should be used.
T1 Bit 23 FTYPE	Filter Type 0 '11-bit standard message ID 1 29-bit extended message ID
T1 Bit 22:16 MNR[6:0]	Message Number Transmission: Trigger is valid for configured Tx Buffer number. Valid values are 0 to 31. Reception: Trigger is valid for standard / extended message ID filter element number. Valid values are 0 to 63 resp. 0 to 127.
T1 Bits 2:0 MSC[2:0]	Message Status Count Counts scheduling errors for periodic messages in exclusive time windows. It has no function for arbitrating messages and in event-driven CAN communication (ISO11898-1). 0-7= Actual status Note: The trigger memory elements have to be written when the M_TTCAN is in INIT state. Write access to the trigger memory elements outside INIT state is not allowed. There is an exception for TMIN and TMEX when they are defined as part of a trigger memory element of TYPE Tx_Ref_Trigger. In this case they become active at the time mark modified by the actual Reference Trigger Offset (TTOST[RTO]).

46.4.7 M_TTCAN functional description

46.4.7.1 Operating modes

46.4.7.1.1 Software initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (=Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_TTCAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write). CCCR[CCE] can only be set/reset while CCCR[INIT] = 1. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set:

- HPMS - High Priority Message Status
- RXF0S - Rx FIFO 0 Status
- RXF1S - Rx FIFO 1 Status
- TXFQS - Tx FIFO/Queue Status
- TXBRP - Tx Buffer Request Pending
- TXBTO - Tx Buffer Transmission Occurred
- TXBCF - Tx Buffer Cancellation Finished
- TXEFS - Tx Event FIFO Status
- TTOST - TT Operation Status
- TTLGT - TT Local and Global Time, only Global Time TTLGT[GT] is reset
- TTCTC - TT Cycle Time and Count
- TTCSM - TT Cycle Sync Mark

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = '1'.

The following registers are only writeable while CCCR[CCE] = '0'

- TXBAR - Tx Buffer Add Request
- TXBCR - Tx Buffer Cancellation Request

CCCR[TEST] and CCCR[MON] can only be set by the Host while CCCR[INIT] = '1' and CCCR[CCE] = '1'. Both bits may be reset at any time. CCCR[DAR] can only be set/reset while CCCR[INIT] = '1' and CCCR[CCE] = '1'.

46.4.7.2 Normal operation

The M_TTCAN's default operating mode after hardware reset is event-driven CAN communication without time triggers (TTOCF[OM] = "00"). It is required that both CCCR[INIT] and CCCR[CCE] are set before the TT Operation Mode can be changed.

Once the M_TTCAN is initialized and CCCR[INIT] is reset to zero, the M_TTCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into the Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

46.4.7.3 CAN FD Operation

There are two stages in the CAN FD protocol, first the Long Frame Mode where the data field of a CAN frame may be longer than 8 bytes. The second stage is the Fast Frame Mode where control field, data field, and CRC field of a CAN Frame are transmitted with a higher

bit rate than the beginning and the end of the frame. Fast Frame Mode can only be used in combination with Long Frame Mode.

The CAN operation mode is chosen by programming CCCR.CME. In case CCCR.CME = g01h transmission of long CAN FD frames and reception of long and fast CAN FD frames is enabled. With CCCR.CME = g10h/g11h transmission and reception of long and fast CAN FD frames is enabled. CCCR.CME can only be changed while CCCR.INIT and CCCR.CCE are both set.

When initialization is left (CCCR.INIT set to e0f), both Long Frame Mode and Fast Frame Mode are inactive, they have to be requested by writing to CCCR.CMR. A mode change requested by writing to CCCR.CMR will be executed next time the CAN protocol

controller FSM reaches idle phase between CAN frames. Upon this event CCCR.CMR is reset to g00h and the status flags CCCR.FACT and CCCR.LACT are set accordingly. In case the requested CAN operation mode is not enabled, the value written to CCCR.CMR is retained until it is overwritten by the next mode change request. Default is normal CAN operation. A change of the CAN operation mode should not be requested while there are pending transmission requests.

When CCCR.CME , g00h, received frames are interpreted according to the CAN FD Protocol Specification. The reserved bit in CAN frames with 11-bit identifiers and the first reserved bit in CAN frames with 29-bit identifiers will be decoded as EDL bit. EDL = recessive signifies a CAN FD long frame, EDL = dominant signifies a standard CAN frame. In a CAN FD long frame, the two bits following EDL, r0 and BRS, decide whether this CAN FD long frame is also a CAN FD fast frame.

A CAN FD fast frame is signified by r0 = dominant and BRS = recessive. The coding of r0 = recessive is reserved for future expansion of the protocol. The status bits CCCR.LACT and CCCR.FACT indicate the format of transmitted frames. When CCCR.LACT is set, frames will be transmitted in CAN FD long format with EDL = recessive. When both CCCR.LACT and CCCR.FACT are set, frames will be transmitted in CAN FD Fast format with both EDL and BRS = recessive.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the following table:

Table 749. Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

In CAN FD fast frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Bit Timing and Prescaler Register BTP. In the following CAN FD data phase, the fast CAN bit timing is used as defined by the Fast Bit Timing and Prescaler Register FBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant,

independent of the transmitter's error state. The data length code of CAN FD remote frames is transmitted as zero.

In case a M_TTCAN Tx Buffer is configured for CAN FD transmission with DLC > 8, the first 8 bytes are transmitted as configured in the Tx Buffer while the remaining part of the data field is padded with 0xCC. When the M_TTCAN receives a CAN FD frame with DLC > 8, the first 8 bytes of that frame are stored into the matching Rx Buffer or Rx FIFO. The remaining bytes are discarded.

46.4.7.4 Transceiver Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin m_ttcn_tx the protocol controller receives the transmitted data from its local CAN transceiver via pin m_ttcn_rx. The received data is delayed by the CAN transceiver's loop delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transceivers loop delay.

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver. Followign figure describes how the transceiver loop delay is measured.

Figure 671. Transceiver delay measurement

Within each CAN FD frame, the transmitter measures the delay between the data transmitted at pin m_ttcn_tx and the data received at pin m_ttcn_rx, starting with the falling edge of bit EDL. The delay is measured in m_ttcn_cclk periods.

A secondary sample point is calculated by adding a configurable transceiver delay compensation offset (FBTP.TDCO) to the measured transceiver delay. The transceiver delay compensation offset is used to adjust the secondary sample point inside the bit time (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of time quanta tq.

To check for bit errors during the data phase, the delayed transmit data is compared against the received data at the secondary sample point. If a bit error is detected at the secondary sample point, the transmitter will react to this bit error at the next following sample point. During arbitration phase the delay compensation is always disabled.

The maximum delay which can be compensated by the M_TTCAN's delay compensation during the data phase is three bit times.

46.4.7.4.1 Configuration and Status

Compensation for the transceiver loop delay by the M_TTCAN is enabled via FBTP.TDC. The transceiver delay compensation offset is configured via FBTP.TDCO. The actual delay compensation value applied by the M_TTCAN's protocol engine can be read from TEST.TDCV.

46.4.7.5 Bus Monitoring mode

The M_TTCAN is set in Bus Monitoring Mode by programming CCCR.MON to one or when error level S3 (TTOST[EL] = "11") is entered. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M_TTCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the M_TTCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_TTCAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode register TXBRP is held in reset state.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. [Figure 672](#) shows the connection of signals M_TTCAN transmit output and M_TTCAN transmit output to the M_TTCAN in Bus Monitoring Mode.

Figure 672. Pin Control in Bus Monitoring Mode

46.4.7.6 Disabled automatic retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_TTCAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic

retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via `CCCR[DAR]`.

46.4.7.7 Frame transmission in DAR mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit `TXBRP.TRPx` is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
 - Corresponding Tx Buffer Transmission Occurred bit `TXBTO[TOx]` set
 - Corresponding Tx Buffer Cancellation Finished bit `TXBCF[CFx]` not set
- Successful transmission in spite of cancellation:
 - Corresponding Tx Buffer Transmission Occurred bit `TXBTO[TOx]` set
 - Corresponding Tx Buffer Cancellation Finished bit `TXBCF[CFx]` set
- Arbitration lost or frame transmission disturbed:
 - Corresponding Tx Buffer Transmission Occurred bit `TXBTO[TOx]` not set
 - Corresponding Tx Buffer Cancellation Finished bit `TXBCF[CFx]` set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type `ET = "10"` (transmission in spite of cancellation).

46.4.7.8 Power down (Sleep mode)

The `M_TTCAN` can be set into power down mode controlled by clock stop request input signal or via CC Control Register `CCCR[CSR]`. As long as the clock stop request signal is active, bit `CCCR[CSR]` is read as one.

When all pending transmission requests have completed, the `M_TTCAN` waits until bus idle state is detected. Then the `M_TTCAN` sets then `CCCR[INIT]` to one to prevent any further CAN transfers. Now the `M_TTCAN` acknowledges that it is ready for power down by setting clock stop acknowledge output signal to one and `CCCR[CSA]` to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to `CCCR[INIT]` will have no effect. Now the module clock inputs `M_TTCAN` host clock and `M_TTCAN` clock may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting clock stop request signal respectively CC Control Register flag `CCCR.CSR`. The `M_TTCAN` will acknowledge this by resetting output clock stop acknowledge signal and resetting `CCCR[CSA]`. Afterwards, the application can restart CAN communication by resetting bit `CCCR[INIT]`.

46.4.7.9 Test modes

To enable write access to register `TEST` (see [Section 46.4.5.2.4, Test Register \(TEST\)](#)), bit `CCCR.TEST` has to be set to one. This allows the configuration of the test modes and test functions. Four output functions are available for the `M_TTCAN` transmit pin by programming `TEST.TX`. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the `M_TTCAN`'s bit timing and it can drive constant dominant or recessive values. The actual value at `M_TTCAN` receive pin can be read from `TEST.RX`. Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST.TX until the new configuration is visible at output pin. This applies also when reading input pin via TEST.RX.

Note: Test modes should be used for production tests or self test only. The software control for M_TTCAN transmit pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

46.4.7.9.1 Watchdog mode

The application watchdog is served by reading register TTOST. When the application watchdog is not served in time, bit TTOST.AWE is set, all M_TTCAN communication is stopped, and the M_TTCAN is set into Bus Monitoring Mode.

The TT Application Watchdog can be disabled by programming the Application Watchdog Limit TTOCF[AWL] to 0x00. The TT Application Watchdog should not be disabled in a M_TTCAN application program.

46.4.7.9.2 External Loop Back mode

The M_TTCAN can be set in External Loop Back mode by programming TEST.LBCK to one. In Loop Back mode, the M_TTCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. [Figure 673](#) shows the connection of transmit and receive signals to the M_TTCAN in External Loop Back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_TTCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/ remote frame) in Loop Back mode. In this mode the M_TTCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the input pin is disregarded by the M_TTCAN. The transmitted messages can be monitored at the transmit pin.

46.4.7.9.3 Internal Loop Back mode

Internal Loop Back mode is entered by programming bits TEST.LBCK and CCCR.MON to one. This mode can be used for a “Hot Selftest”, meaning the M_TTCAN can be tested without affecting a running CAN system connected to the M_TTCAN Tx and Rx pins. In this mode pin Rx pin is disconnected from the M_TTCAN and Tx pin is held recessive. [Figure 673](#) shows the connection of M_TTCAN TX and _TTCAN Rx to the M_TTCAN in case of Internal Loop Back Mode.

Figure 673. Pin Control in Loop Back modes

46.4.7.10 Timestamp generation

For timestamp generation the M_TTCAN supplies a 16-bit wrap-around counter. A prescaler TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1...16). The counter is readable via TSCV[TCV]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of a Rx Buffer/ Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit TSCC.TSS, a 16-bit timestamp can be used.

46.4.7.11 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_TTCAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The Timeout Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC].

The Timeout Counter can only be started while CCCR[INIT] = '0'. It is stopped when CCCR[INIT] = '1', e.g. when the M_TTCAN enters Bus_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs/FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous mode, the counter is immediately restarted at TOCC[TOP].

Note: The clock signal for the Timeout Counter is derived from the CAN core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN core. If the baud rate

switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

46.4.7.12 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

46.4.7.12.1 Acceptance filtering

The M_TTCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx buffer, Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
 - range filter (from - to)
 - filter for one or two dedicated IDs
 - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Reject received frame
- Set High Priority Message interrupt flag IR[HPM]
- Set High Priority Message interrupt flag IR[HPM] and store received frame in FIFO 0 or FIFO 1

Note: When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

46.4.7.12.2 Range filter

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames: EFT = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask

(XIDAM) before the range filter is applied EFT = "11": The Extended ID AND Mask (XIDAM) is not used for range filtering

46.4.7.12.3 Filter for dedicated IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID=SF2ID resp.EF1ID=EF2ID.

46.4.7.12.4 Classic bit mask filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID /EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

46.4.7.12.5 Standard message ID filtering

[Figure 674](#) below shows the flow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in [Section 46.4.6.4, Standard message ID Filter element](#).

Controlled by the Global Filter Configuration (GFC) and the Standard ID Filter Configuration (SIDFC) Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements

Figure 674. Standard Message ID Filter Path

46.4.7.12.6 Extended message ID filtering

Figure 675 below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in [Section 46.4.6.5, Extended message ID filter element](#).

Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements which is controlled by the Global Filter Configuration (GFC) and the Extended ID Filter Configuration (XIDFC) Message ID. The Extended ID AND Mask (XIDAM) is ANDed with the received identifier before the filter list is executed.

Figure 675. Extended Message ID Filter Path

46.4.7.13 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, see [Section 46.4.7.12.1, Acceptance filtering](#). The Rx buffer and FIFO element is described in [Section 46.4.7.13, Rx FIFOs](#).

When an Rx FIFO full condition is signaled by IR[RxFnF]], no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO

Get Index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded and interrupt flag IR[RFnL] is set.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC[FnWM], interrupt flag IR[RFnW] is set.

When reading from an Rx FIFO, four times the Rx FIFO Get Index RXFnS[FnGI] has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

46.4.7.14 Dedicated Rx Buffers

The M_TTCAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC.RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = "111" and SFID2 / EFID2[10:9] = "00" has to be configured (see [Section 46.4.6.4, "Standard message ID Filter element"](#) and [Section 46.4.6.5, "Extended message ID filter element"](#)).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 750. Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

46.4.7.14.1 Rx Buffer Handling

- Reset interrupt flag IR.DRX
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

46.4.7.15 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The Tx Buffer element is described in [Section 46.3.6.2, Tx buffer element](#). The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

Note: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

46.4.7.16 Dedicated Tx buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first. If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding four times the transmit buffer index (0...31) to the Tx Buffer Start Address TXBC[TBSA].

46.4.7.17 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_TTCAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements. New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF]= '1') is signaled.

In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index. When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding four times the Put Index TXFQS[TFQPI] (0...31) to the Tx Buffer Start Address TXBC[TBSA].

46.4.7.18 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. New messages have to be written to the Tx Buffer referenced by the Put Index

TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = '1'), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates four 32-bit words in the Message RAM. Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding four times the Tx Queue Put Index TXFQS[TFQPI] (0...31) to the Tx Buffer Start Address TXBC[TBSA].

46.4.7.19 Mixed dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case, TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 676. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

46.4.7.20 Mixed dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by

TXBC[NDTB]. The number of Tx Queue Buffers is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only dedicated Tx Buffers are used.

Figure 677. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

46.4.7.21 Transmit cancellation

The M_TTCAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation. Successful cancellation is signaled by setting the corresponding bit of register TXBCF to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

Note: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

46.4.7.22 Tx Event handling

To support Tx event handling the M_TTCAN has implemented a Tx Event FIFO. After the M_TTCAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element. The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in [Section 46.3.6.3, Tx event FIFO element](#). When a Tx Event FIFO full condition is signaled by IR[TEFF], no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR[TEFW] is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

46.4.8 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see [Section 46.4.5.2.27, Rx FIFO 0 Acknowledge Register \(RXF0A\)](#), [Section 46.4.5.2.31, Rx FIFO 1 Acknowledge Register \(RXF1A\)](#), and [Section 46.4.5.2.41, Tx Event FIFO Configuration Register \(TXEFC\)](#)). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index. When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M_TTCAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.

46.4.9 M_TTCAN operations

46.4.9.1 Reference message

A reference message is a data frame characterized by a specific CAN identifier. It is received and accepted by all nodes except the Time Master (sender of the reference message). For Level 1 the data length must be at least one; for Level 0, 2 the data length must be at least four; otherwise, the message is not accepted as reference message. The reference message may be extended by other data up to the sum of eight CAN data bytes. All bits of the identifier except the three LSBs characterize the message as a reference message. The last three bits specify the priorities of up to eight potential time masters. Reserved bits are transmitted as logical 0 and are ignored by the receivers. The reference message is configured via register TTRMC. The time master transmits the reference message. If the reference message is disturbed by an error, it is retransmitted immediately. In case of a retransmission, the transmitted **Master_Ref_Mark** is updated. The reference message is sent periodically, but is allowed to stop the periodic transmission (**Next_is_Gap** bit) and to initiate transmission event-synchronized at the start of the next basic cycle by the current time master or by one of the other potential time masters. The node transmitting the reference message is the current time master. The time master is allowed to transmit other messages. If the current time master fails, its function is replicated by the potential time master with the highest priority. Nodes that are neither time master nor potential time master are time-receiving nodes.

46.4.9.2 Level 1

Level 1 operation is configured via TTOCF[OM] = “01” and TTOCF[GEN]. External clock synchronization is not available in Level 1. The information related to the reference message is stored in the first data byte as shown below. Cycle_Count is optional.

Figure 678. First byte of Level 1 reference message

46.4.9.3 Level 2

Level 2 operation is configured via TTOCF[OM] = “10” and TTOCF[GEN]. The information related to the reference message is stored in the first four data bytes as shown below. Cycle_Count and the lower four bits of NTU_Res are optional. The M_TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

Figure 679. First four bytes of Level 2 reference message

46.4.9.4 Level 0

Level 0 operation is configured via TTOCF[OM] = “11”. External event-synchronized time-triggered operation is not available in Level 0. The information related to the reference message is stored in the first four data bytes as shown in the table below. In Level 0 Next_is_Gap is always zero. Cycle_Count and the lower four bits of NTU_Res are optional. The M_TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as zero.

Figure 680. First four bytes of Level 0 reference message

46.4.10 M_TTCAN configuration

46.4.10.1 M_TTCAN timing

The Network Time Unit NTU is the unit in which all times are measured. The NTU is a constant of the whole network and is defined a priority by the network system designer. In M_TTCAN Level 1 the NTU is the nominal CAN bit time. In M_TTCAN Level 0 and Level 2 the NTU is a fraction of the physical second.

The NTU is the time base for the local time. The integer part of the local time (16-bit value) is incremented once each NTU. Cycle time and global time are both derived from local time. The fractional part (3-bit value) of local time, cycle time, and global time is not readable. In M_TTCAN Level 0 and Level 2 the length of the NTU is defined by the Time Unit Ratio TUR. The TUR is in general a non-integer number, given by the formula $TUR = \frac{TURNA[NAV]}{TURCF[DC]}$. The length of the NTU is given by the formula $NTU = \text{CAN Clock Period} \times TUR$. The TUR Numerator Configuration NC is an 18-bit number, $TURCF[NCL[15:0]]$ can be programmed in the range 0x0000–0xFFFF. $TURCF[NCH[17:16]]$ is hard wired to 0b01. When the number 0xn timer is written to $TURCF[NCL[15:0]]$, $TURNA[NAV]$ starts with the value $0x10000 + 0x0nnnn = 0x1nnnn$. The TUR Denominator Configuration $TURCF[DC]$ is a 14-bit number. $TURCF[DC]$ may be programmed in the range 0x0001 - 0x3FFF, 0x0000 is an illegal value.

In Level 1, NC must be $\geq 4 \times TURCF[DC]$. In Level 0, 2 NC must be $\geq 8 \times TURCF[DC]$ to allow the 3-bit resolution for the internal fractional part of the NTU.

A hardware reset presets $TURCF[DC]$ to 0x1000 and $TURCF[NCL]$ to 0x10000, resulting in an NTU consisting of 16 CAN clock periods. Local time and application watchdog are not started before either the $CCCR[INIT]$ is reset, or $TURCF[ELT]$ is set. $TURCF[ELT]$ may not be set before the NTU is configured. Setting $TURCF[ELT]$ to e1f also locks the write access to register $TURCF$.

At startup $TURNA[NAV]$ is updated from NC ($= TURCF[NCL] + 0x10000$) when $TURCF[ELT]$ is set. In M_TTCAN Level 1 there is no drift compensation. $TURNA.NAV$ does not change during operation, it always equals NC.

In M_TTCAN Level 0 and Level 2 there are two possibilities for $TURNA[NAV]$ to change. When operating as time slave or backup time master, and when $TTOCF[ECC]$ is set, $TURNA[NAV]$ is updated automatically to the value calculated from the monitored global time speed, as long as the M_TTCAN is in synchronization state In_Schedule or In_Gap. When it loses synchronization it returns to NC. When operating as the actual time master,

and when TTOCF[EECS] is set, the Host may update TURCF[NCL]. When the Host sets TTOCN[ECS], TURNA[NAV] will be updated from the new value of NC at the next reference message. The status flag TTOST[WECS] as is set when TTOCN[ECS] is set and is cleared when TURNA[NAV] is updated. TURCF[NCL] is write locked while TTOST[WECS] is set.

In M_TTCAN Level 0 and Level 2 the clock calibration process adapts TURNA[NAV] in the range of the Synchronization Deviation Limit SDL of $NC \pm 2^{(TTOCF[LDSDL]+5)}$. TURCF[NCL] should be programmed to the largest applicable numerical value in order to achieve the best accuracy in the calculation of TURNA[NAV].

The synchronization deviation SD is the difference between NC and TURNA[NAV] ($SD = |NC - TURNA[NAV]|$). It is limited by the Synchronization Deviation Limit SDL, which is configured by its dual logarithm TTOCF[LDSDL] ($SDL = 2^{(TTOCF[LDSDL]+5)}$) and should not exceed the clock tolerance given by the CAN bit timing configuration. SD is calculated at each new Basic Cycle. When the calculated TURNA[NAV] deviates by more than SDL from NC, or if the Disc_Bit in the Reference Message is set, the drift compensation is suspended and TTIR[GTE] is set and TTOSC[QCS] is reset, or in case of the Disc_Bit = '1', TTIR[GTD] is set.

TUR	8	10	24	50	510	125000	32.5	100/12	529/17
NC	0x1FFF8	0x1FFFE	0x1FFF8	0x1FFFEA	0x1FFFE	0x1E848	0x1FFE0	0x19000	0x10880
TURCF.DC	0x3FFF	0x3333	0x1555	0x0A3D	0x0101	0x0001	0x0FC0	0x3000	0x0880

Figure 681. TUR configuration examples

TTOCN[ECS] schedules NC for activation by the next reference message. TTOCN[SGT] schedules TTGTP[TP] for activation by the next reference message. Setting of TTOCN[ECS] and TTOCN[SGT] requires TTOCF[EECS] to be set (external clock synchronization enabled) while the M_TTCAN is actual time master. The M_TTCAN module provides an application watchdog to verify the function of the application program. The Host has to serve this watchdog regularly, else all CAN bus activity is stopped. The Application Watchdog Limit TTOCF[AWL] specifies the number of NTUs between two times the watchdog has to be served. The maximum number of NTUs is 256. The Application Watchdog is served by reading register TTOST. TTOST[AWE] indicates whether the watchdog has been served in time. In case the application failed to serve the application watchdog, interrupt flag TTIR[AW] is set. For software development, the application watchdog may be disabled by programming TTOCF[AWL] to 0x00 (see also Section 46.4.7.9.1).

46.4.10.2 Timing of interface signals

The timing events which cause a pulse at output M_TTCAN trigger time mark interrupt pulse and M_TTCAN register time mark interrupt pulse are generated in the CAN clock domain. There is a clock domain crossing delay to be considered before the same event is visible in the Host clock domain (TTIR[TTMI] resp. TTIR[RTMI] set). The signals can be connected e.g. to the timing input(s) of another M_TTCAN node, in order to automatically synchronize two M_TTCAN networks. Output M_TTCAN start of cycle gets active whenever a reference message is completed (either transmitted or received). The output is controlled in the Host clock domain.

46.4.11 Message scheduling

TTOCF[TM] controls whether the M_TTCAN operates as a potential time master or as a time slave. If it is a potential time master, the three LSBs of the reference message's identifier TTRMC[RID] define the master priority, 0 giving the highest and 7 giving the lowest priority. There may not be two nodes in the network using the same master priority. TTRMC[RID] is used for recognition of reference messages. TTRMC[RMPS] is not relevant for time slaves. The Initial Reference Trigger Offset TTOCF[IRTO] is a 7-bit-value that defines (in NTUs) how long a backup time master waits before it starts the transmission of a reference message when a reference message is expected but the bus remains idle. The recommended value for TTOCF[IRTO] is the master priority multiplied with a factor depending on the expected clock drift between the potential time masters in the network. The sequential order of the backup time masters, when one of them starts the reference message in case the current time master fails, should correspond to their master priority, even with maximum clock drift.

TTOCF[OM] decides whether the node operates in M_TTCAN Level 0, Level 1, or Level 2. In one network, all potential time masters have to operate on the same level. Time slaves may operate on Level 1 in a Level 2 network, but not vice versa. TTOCF[EECS] enables the external clock synchronisation, allowing the application program of the current time master to update the TUR configuration during time-triggered operation, to adapt the clock speed and (in Level 0, 2 only) the global clock phase to an external reference.

The configuration of the M_TTCAN operation mode via TTOCF[OM] is the last step in the setup. With TTOCF[OM] = "00" (event-driven CAN communication), the M_TTCAN operates according to ISO 11898-1, without time triggers. With TTOCF[OM] = "01" (Level 1), the M_TTCAN operates according to ISO 11898-4, but without the possibility to synchronize the basic cycles to external events, the **Next is Gap** bit in the reference message is ignored. With TTOCF[OM] = "10" (Level 2), the M_TTCAN operates according to ISO 11898-4, including the event-synchronized start of a basic cycle. With TTOCF[OM] = "11" (Level 0), the M_TTCAN operates as event-driven CAN but maintains a calibrated global time base as in Level 2.

TTOCF[EECS] enables the external clock synchronisation, allowing the application program of the current time master to update the TUR configuration during time-triggered operation, to adapt the clock speed and (in Level 0,2 only) the global clock phase to an external reference.

TTMLM[ENTT] in the TT Matrix Limits register specifies the number of expected Tx_Triggers in the system matrix. This is the sum of Tx_Triggers for exclusive, single arbitrating and merged arbitrating windows, excluding the Tx_Ref_Triggers. Note that this is usually not the number of Tx_Trigger memory elements; the number of basic cycles in the system matrix and the trigger's repeat factors have to be taken into account. An inaccurate configuration of TTMLM[ENTT] will result in either a TxCount Underflow (TTIR[TXU] = '1' and TTOST[EL] = "01", severity 1) or in a Tx Count Overflow (TTIR[TXO] = '1' and TTOST[EL] = "10", severity 2).

Note: In case the first Reference Message seen by a node does not have Cycle_Count zero, this node may finish its first matrix cycle with its Tx count resulting in a Tx Count Underflow condition. As long as a node is in state Synchronizing its Tx_Triggers will not lead to transmissions.

TTMLM[CCM] specifies the number of the last basic cycle in the system matrix. The counting of basic cycles starts at 0. In a system matrix consisting of 8 basic cycles TTMLM[CCM] would be 7. TTMLM[CCM] is ignored by time slaves, a receiver of a

reference message considers the received cycle count as the valid cycle count for the actual basic cycle. TTMLM[TXEW] specifies the length of the Tx enable window in NTUs. The Tx enable window is that period of time at the beginning of a time window where a transmission may be started. If a transmission of a message cannot be started inside the Tx enable window because of for example, a slight overlap from the previous time window's message, the transmission cannot be started in that time window at all. TTMLM[TXEW] has to be chosen with respect to the network's synchronisation quality and with respect to the relation between the length of the time windows and the length of the messages.

46.4.11.1 Trigger memory

The trigger memory is part of the external Message RAM to which the M_TTCAN is connected via its Generic Master Interface (see [Figure 585](#)). It stores up to 64 trigger elements. A trigger memory element consists of Time Mark TM, Cycle Code CC, Trigger Type TYPE, Filter Type FTYPE, Message Number MNR, Message Status Count MSC, Time Mark Event Internal TMIN, Time Mark Event External TMEX, and Asynchronous Serial Communication ASC (see [Section 46.4.6.6, Trigger memory element](#)).

The time mark defines at which cycle time a trigger becomes active. The triggers in the trigger memory have to be sorted by their time marks. The trigger element with the lowest time mark is written to the first trigger memory word. Message number and cycle code are ignored for triggers of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, and End_of_List. When the cycle time reaches the time mark of the actual trigger, the FSE switches to the next trigger and starts to read the following trigger from the trigger memory. In case of a transmit trigger, the Tx Handler starts to read the message from the Message RAM as soon as the FSE switches to its trigger. The RAM access speed defines the minimum time step between a transmit trigger and its preceding trigger, the Tx Handler has to be able to prepare the transmission before the transmit trigger's time mark is reached. The RAM access speed also limits the number of non-matching (with regard to their cycle code) triggers between two matching triggers, the next matching trigger must be read before its time mark is reached. If the reference message is n NTU long, a trigger with a time mark $< n$ will never become active and will be treated as a configuration error. Starting point of the cycle time is the sample point of the reference message's start of frame bit. The next reference message is requested when cycle time reaches the Tx_Ref_Trigger's time mark. The M_TTCAN reacts on the transmission request at the next sample point. A new Sync_Mark is captured at the start of frame bit, but the cycle time is incremented until the reference message is successfully transmitted (or received) and the Sync_Mark is taken as the new Ref_Mark. At that point in time, cycle time is restarted. As a consequence, cycle time can never (with the exception of initialisation) be seen at a value $< n$, with n being the length of the reference message measured in NTU.

Length of a basic cycle: Tx_Ref_Trigger's time mark+1 NTU+1 CAN bit time.

The trigger list will be different for all nodes in the M_TTCAN network. Each node knows only the Tx_Triggers for its own transmit messages, the Rx_Triggers for those receive messages that are processed by this node, and the triggers concerning the reference messages.

46.4.11.1.1 Trigger types

Tx_Ref_Trigger (**TYPE** = "0000") and Tx_Ref_Trigger_Gap (**TYPE** = "0001") cause the transmission of a reference message by a time master. A configuration error (**TTOST[EL]** = "11", severity 3) is detected when a time slave encounters a Tx_Ref_Trigger(_Gap) in its trigger memory. Tx_Ref_Trigger_Gap is only used in external event-synchronised time-triggered operation mode. In that mode, Tx_Ref_Trigger is ignored when the M_TTCAN

synchronisation state is In_Gap (**TTOST[SYS]** = "10"). Tx_Trigger_Single (**TYPE** = "0010"), Tx_Trigger_Continuous (**TYPE** = "0011"), Tx_Trigger_Arbitration (**TYPE** = "0100"), and Tx_Trigger_Merged (**TYPE** = "0101") cause the start of a transmission. They define the start of a time window.

Tx_Trigger_Single starts a single transmission in an exclusive time window when the message buffer's Transmission Request Pending bit is set. After successful transmission the Transmission Request Pending bit is reset. Tx_Trigger_Continuous starts a transmission in an exclusive time window when the message buffer's Transmission Request Pending bit is set. After successful transmission the Transmission Request Pending bit remains set, and the message buffer is transmitted again in the next matching time window.

Tx_Trigger_Arbitration starts an arbitrating time window, Tx_Trigger_Merged a merged arbitrating time window. The last Tx_Trigger of a merged arbitrating time window must be of type Tx_Trigger_Arbitration. A Configuration Error (**TTOST[EL]** = "11", severity 3) is detected when a trigger of type Tx_Trigger_Merged is followed by any other Tx_Trigger than one of type Tx_Trigger_Merged or Tx_Trigger_Arbitration. Several Tx_Triggers may be defined for the same Tx message buffer. Depending on their cycle code, they may be ignored in some basic cycles. The cycle code has to be considered when the expected number of Tx_Triggers (**TTMLM[ENTT]**) is calculated.

Watch_Trigger (**TYPE** = "0110") and Watch_Trigger_Gap (**TYPE** = "0111") check for missing reference messages. They are used by both time masters and time slaves.

Watch_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, a Watch_Trigger is ignored when the M_TTCAN synchronisation state is In_Gap (**TTOST[SYS]** = "10"). Rx_Trigger (**TYPE** = "1000") is used to check for the reception of periodic messages in exclusive time windows. Rx_Triggers are not active until state In_Schedule or In_Gap is reached. The time mark of an Rx_Trigger shall be placed after the end of that message's transmission, independent of time window boundaries. Depending on their cycle code, Rx_Triggers may be ignored in some basic cycles. At the time mark of the Rx_Trigger, it is checked whether the last received message before this time mark and after start of cycle or previous Rx_Trigger had matched the acceptance filter element referenced by **MNR**. Accepted messages are stored in one of the two receive FIFOs, according to the acceptance filtering, independent of the Rx_Trigger. Acceptance filter elements which are referenced by Rx_Triggers should be placed at the beginning of the filter list to ensure that the filtering is finished before the Rx_Trigger's time mark is reached.

Time_Base_Trigger (**TYPE** = "1001") are used to generate internal/external events depending on the configuration of **ASC**, **TMIN**, and **TMEX**. End_of_List (**TYPE** = "1010...1111") is an illegal trigger type, a configuration error (**TTOST[EL]** = "11", severity 3) is detected when an End_of_List trigger is encountered in the trigger memory before the Watch_Trigger.

46.4.11.1.2 Restrictions for the node's trigger list

There may not be two triggers that are active at the same cycle time and cycle count, but triggers that are active in different basic cycles (different cycle code) may share the same time mark. Rx_Triggers and Time_Base_Triggers may not be placed inside the Tx enable windows of Tx_Trigger_Single/Continuous/Arbitration, but they may be placed after Tx_Trigger_Merged or Tx_Ref_Trigger. Triggers that are placed after the Watch_Trigger (or the Watch_Trigger_Gap when **TTOST[SYS]** = "10") will never become active. The watch triggers themselves will not become active when the reference messages are transmitted on time. All unused trigger memory words (after the Watch_Trigger or after the Watch_Trigger_Gap when **TTOST[SYS]** = "10") must be set to trigger type End_of_List. A

typical trigger list for a potential time master will begin with a number of Tx_Triggers and Rx_Triggers followed by the Tx_Ref_Trigger and the Watch_Trigger. For networks with external event- synchronized time-triggered communication, this is followed by the Tx_Ref_Trigger_Gap and the Watch_Trigger_Gap. The trigger list for a time slave will be the same but without the Tx_Ref_Trigger and the Tx_Ref_Trigger_Gap.

At the beginning of each basic cycle, that is at each reception or transmission of a reference message, the trigger list is processed starting with the first trigger memory element. The FSE looks for the first trigger with a cycle code that matches the current cycle count. The FSE waits until cycle time reaches the trigger's time mark and activates the trigger. Afterwards the FSE looks for the next trigger in the list with a cycle code that matches the current cycle count.

Special consideration is needed for the time around Tx_Ref_Trigger and Tx_Ref_Trigger_Gap. In a time master competing for master ship, the effective time mark of a Tx_Ref_Trigger may be decremented in order to be the first node to start a reference message. In backup time masters the effective time mark of a Tx_Ref_Trigger or Tx_Ref_Trigger_Gap is the sum of its configured time mark and the Reference Trigger Offset **TTOCF[IRTO]**. In case error level 2 is reached (**TTOST[EL]** = "10"), the effective time mark is the sum of its time mark and 0x127. No other trigger elements should be placed in this range otherwise it may happen, that the time marks appear out of order and are flagged as a configuration error. Trigger elements which are coming after Tx_Ref_Trigger may never become active as long as the reference messages come in time.

There are interdependencies between the following parameters:

- Host clock frequency
- Speed and waiting time for Trigger RAM accesses
- Length of the acceptance filter list
- Number of trigger elements
- Complexity of cycle code filtering in the trigger elements
- Offset between time marks of the trigger elements

46.4.11.1.3 Example for trigger handling

The example below shows how the trigger list is derived from a node's system matrix. Assumed node A is first time master and has knowledge of the section of the system matrix shown below.

Table 751. System Matrix Node A

Cycle Count	Time Mark1	Time Mark2	Time Mark3	Time Mark4	Time Mark5	Time Mark6	Time Mark7
0	Tx7					TxRef	Error
1	Rx3		Tx2, Tx4			TxRef	Error
2						TxRef	Error
3	Tx7		Rx5			TxRef	Error
4	Tx7			Rx6		TxRef	Error

The cycle count starts with 0 and runs until 0, 1, 3, 7, 15, 31, 63 (the number of basic cycles in the system matrix is 1, 2, 4, 8, 16, 32, 64). The maximum cycle count is configured by

TTMLM.CCM. The Cycle Code CC is composed of repeat factor (= value of most significant '1') and the number of the first basic cycle in the system matrix (= bit field after most significant '1'). Example: with a cycle code of 0b0010011 (repeat factor: 16, first basic cycle: 3) and a maximum cycle count of TTMLM.CCM = "0x3F" matches occur at cycle counts 3, 19, 35, 51.

A trigger element consists of Time Mark TM, Cycle Code CC, Trigger Type TYPE, and Message Number MNR. For transmission MNR references the Tx Buffer number (0..31). For reception MNR references the number of the filter element (0..127) that matched during acceptance filtering. Depending on the configuration of the Filter Type FTYPE, the 11-bit or 29-bit message ID filter list is referenced.

In addition a trigger element can be configured for Asynchronous Serial Communication ASC, generation of Time Mark Event Internal TMIN, and Time Mark Event External TMEX. The Message Status Count MSC holds the counter value (0..7) for scheduling errors for periodic messages in exclusive time windows at the point in time when the time mark of the trigger element became active.

Table 752. Trigger List Node A

Trigger	Time Mark TM[15:0]	Cycle Code CC [6:0]	Trigger Type TYPE [3:0]	Mess No. MNR [6:0]
0	Mark 1	0b0000100	Tx_Trigger_Single	7
1	Mark 1	0b1000000	Rx_Trigger	3
2	Mark 1	0b1000011	Tx_Trigger_Single	7
3	Mark 3	0b1000001	Tx_Trigger_Merged	2
4	Mark 3	0b1000011	Rx_Trigger	5
5	Mark 4	0b1000001	Tx_Trigger_Arbitration	4
6	Mark 4	0b1000100	Rx_Trigger	6
7	Mark 6	n.a.	Tx_Ref_Trigger	0 (Ref)
8	Mark 7	n.a.	Watch_Trigger	n.a.
9	n.a.	n.a.	End_of_List	n.a.

Tx_Trigger_Single, Tx_Trigger_Continuous, Tx_Trigger_Merged, Tx_Trigger_Arbitration, Rx_Trigger, and Time_Base_Trigger are only valid for the specified cycle code. For all other trigger types the cycle code is ignored. The FSE starts the basic cycle with scanning the trigger list starting from zero until a trigger with time mark > cycle time and with its Cycle Code **CC** matching the actual cycle count is reached, or a trigger of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, or Watch_Trigger_Gap is encountered. When the cycle time reached the Time Mark **TM**, the action defined by Trigger Type **TYPE** and Message Number **MNR** is started. There is an error in the configuration when End_of_List is reached.

At Mark6 the reference message (always TxRef) is transmitted. After transmission of the reference message the FSE returns to the beginning of the trigger list. When the Watch Trigger at Mark7 is reached, the node was not able to transmit the reference message; error treatment is started.

46.4.11.1.4 Detection of configuration errors

A configuration error is signaled via **TTOST[EL]** = "11" (severity 3) when: The FSE comes to a trigger in the list with a cycle code that matches the current cycle count but with a time mark that is less than the cycle time. The previous active trigger was a Tx_Trigger_Merged and the FSE comes to a trigger in the list with a cycle code that matches the current cycle count but that is neither a Tx_Trigger_Merged nor a Tx_Trigger_Arbitration nor a Time_Base_Trigger nor an Rx_Trigger. The FSE of a node with **TTOCF[TM]** = '0' (time slave) encounters a Tx_Ref_Trigger or a Tx_Ref_Trigger_Gap.

Any time mark placed inside the Tx enable window (defined by **TTMLM[TXEW]**) of a Tx_Trigger with a matching cycle code. A time mark is placed near the time mark of a Tx_Ref_Trigger and the Reference Trigger Offset **TTOST[RTO]** causes a reversal of their sequential order measured in cycle time.

46.4.11.2 M_TTCAN schedule initialization

The synchronisation to the M_TTCAN's message schedule starts when **CCCR[INIT]** is reset. The M_TTCAN can operate strictly time-triggered (**TTOCF[GEN]** = '0') or external event-synchronized time-triggered (**TTOCF[GEN]** = '1'). All nodes start with cycle time zero at the beginning of their trigger list with **TTOST[SYS]** = "00" (out of synchronisation), no transmission is enabled with the exception of the reference message. Nodes in external event-synchronised time-triggered operation mode will ignore Tx_Ref_Trigger and Watch_Trigger and will use instead Tx_Ref_Trigger_Gap and Watch_Trigger_Gap until the first reference message decides whether a Gap is active.

46.4.11.2.1 Time slaves

After configuration, a time slave will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message before reaching the Watch_Triggers. When it reaches Init_Watch_Trigger, interrupt flag **TTIR[IWT]** is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). The first received reference message will restart the FSE and the cycle time.

Note: Init_Watch_Trigger is not part of the trigger list. It is implemented as an internal counter which counts up to 0xFFFF = maximum cycle time.

When a time slave has received any message but the reference message before reaching the Watch_Triggers, it will assume a fatal error (**TTOST[EL]** = "11", severity 3), set interrupt flag **TTIR[WT]**, switch off its CAN bus output, and enter the bus monitoring mode (**CCCR[MON]** set to '1'). In the bus monitoring mode it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

Note: To leave the fatal error state, the Host has to set CCCR[INIT] = '1'. After reset of CCCR[INIT], the node restarts M_TTCAN communication.

When no error is encountered during synchronisation, the first reference message sets **TTOST[SYS]** = "01" (Synchronizing), the second sets the M_TTCAN synchronization state (depending on its Next_is_Gap bit) to **TTOST[SYS]** = "11" (In_Schedule) or **TTOST[SYS]** = "10" (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

46.4.11.2.2 Potential time masters

After configuration, a potential time master will start the transmission of a reference message when it reaches its Tx_Ref_Trigger (or its Tx_Ref_Trigger_Gap when in external event-synchronized time-triggered operation). It will ignore its Watch_Trigger and

Watch_Trigger_Gap when it did not receive any message or transmit the reference message successfully before reaching the Watch_Triggers (assumed reason: all other nodes still in reset or configuration, giving no acknowledge). When it reaches Init_Watch_Trigger, the attempted transmission is aborted, interrupt flag **TTIR[IWT]** is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). Resetting **TTIR[IWT]** will re-enable the transmission of reference messages until next time the Init_Watch_Trigger condition is met, or another CAN message is received. The FSE will not be restarted by the reception of a reference message.

When a potential time master reaches the Watch_Triggers after it has received any message but the reference message, it will assume a fatal error (**TTOST[EL]** = "11", severity 3), set interrupt flag **TTIR[WT]**, switch off its CAN bus output, and enter the bus monitoring mode (**CCCR[MON]** set to '1'). In bus monitoring mode, it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

When no error is detected during initialization, the first reference message sets **TTOST[SYS]** = "01" (synchronizing), the second sets the M_TTCAN synchronization state (depending on its **Next_is_Gap** bit) to **TTOST[SYS]** = "11" (In_Schedule) or **TTOST[SYS]** = "10" (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

A potential time master is current time master (**TTOST[MS]** = "11") when it was the transmitter of the last reference message, else it is backup time master (**TTOST[MS]** = "10").

When all potential time masters have finished configuration, the node with the highest time master priority in the network will become the current time master.

46.4.12 M_TTCAN gap control

All functions related to Gap control apply only when the M_TTCAN is operated in external event synchronized time-triggered mode (**TTOCF[GEN]** = '1'). In this operation mode the M_TTCAN message schedule may be interrupted by inserting Gaps between the basic cycles of the system matrix. All nodes connected to the CAN network have to be configured for external event- synchronized time-triggered operation.

During a Gap, all transmissions are stopped and the CAN bus remains idle. A Gap is finished when the next reference message starts a new basic cycle. A Gap starts at the end of a basic cycle that itself was started by a reference message with bit **Next_is_Gap** = '1' e.g. Gaps are initiated by the current time master.

The current time master has two options to initiate a Gap. A Gap can be initiated under software control when the application program writes **TTOCN[NIG]** = '1'. The **Next_is_Gap** bit will be transmitted as '1' with the next reference message. A Gap can also be initiated under hardware control when the application program enables the event trigger input pin by writing **TTOCN[GCS]** = '1'. When a reference message is started and **TTOCN[GCS]** is set, a HIGH level at event trigger pin will set **Next_is_Gap** = '1'.

As soon as that reference message is completed, the **TTOST[WFE]** bit will announce the Gap to the time master as well as to the time slaves. The current basic cycle will continue until its last time window. The time after the last time window is the Gap time.

For the actual time master and the potential time masters, **TTOST[GS]** will be set when the last basic cycle has finished and the Gap time starts. In nodes that are time slaves, bit **TTOST[GS]** will remain at '0'.

When a potential time master is in synchronization state `In_Gap` (`TTOST[SYS] = "10"`), it has four options to intentionally finish a Gap:

Under software control by writing `TTOCN[FGP] = '1'`.

Under hardware control (`TTOCN[GCS] = '1'`) an edge from HIGH to LOW at the event-trigger input pin sets `TTOCN[FGP]` and restarts the schedule.

The third option is a time-triggered restart. When `TTOCN[TMG] = '1'`, the next register time mark interrupt (`TTIR[RTMI] = '1'`) will set `TTOCN[FGP]` and start the reference message.

Finally any potential time master will finish a Gap when it reaches its `Tx_Ref_Trigger_Gap`, assuming that the event to synchronize on did not occur in time.

Neither of these options can cause a basic cycle to be interrupted with a reference message. Setting of `TTOCN[FGP]` after the Gap time has started will start the transmission of a reference message immediately and will thereby synchronize the message schedule. When `TTOCN[FGP]` is set before the Gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the `Tx_Ref_Trigger` – there will be no Gap time in the message schedule.

In strictly time-triggered operation, bit `Next_is_Gap` = '1' in the reference message will be ignored, as well as the event-trigger input pin and the bits `TTOCN[NIG]`, `TTOCN[FGP]`, and `TTOCN[TMG]`.

46.4.13 Stop watch

The stop watch function enables capturing of M_TTCAN internal time values (local time, cycle time, or global time) triggered by an external event. To enable the stop watch function, the application program first has to define local time, cycle time, or global time as stop watch source via `TTOCN[SWS]`. When `TTOCN[SWS]` is $\neq$ '00' and TT Interrupt Register flag `TTIR[SWE]` is '0', the actual value of the time selected by `TTOCN[SWS]` will be copied into `TTCPT[SWV]` on the next rising/falling edge (as configured via `TTOCN[SWP]`) on stop watch trigger pin. This will set interrupt flag `TTIR[SWE]`. After the application program has read `TTCPT[SWV]`, it may enable the next stop watch event by resetting `TTIR[SWE]` to '0'.

46.4.14 Local time, cycle time, global time, and external clock synchronization

There are two possible levels in time-triggered CAN: Level 1 and Level 2. Level 1 only provides time-triggered operation using cycle time. Level 2 additionally provides increased synchronisation quality, global time and external clock synchronisation. In both levels, all timing features are based on a local time base - the local time. The local time is a 16-bit cyclic counter, it is incremented once each NTU. Internally the NTU is represented by a 3-bit counter which can be regarded as a fractional part (three binary digits) of the local time. Generally, the 3-bit NTU counter is incremented 8 times each NTU. If the length of the NTU is shorter than 8 CAN clock periods (as may be configured in Level 1, or as a result of clock calibration in Level 2), the length of the NTU fraction is adapted, and the NTU counter is incremented only 4 times each NTU.

[Figure 682](#) describes the synchronisation of the cycle time and global time, performed in the same manner by all M_TTCAN nodes, including the time master. Any message received or transmitted invokes a capture of the local time taken at the message is frame synchronisation event. This frame synchronisation event occurs at the sample point of each Start of Frame (SoF) bit and causes the local time to be stored as `Sync_Mark`. `Sync_Marks` and `Ref_Marks` are captured including the 3-bit fractional part.

Whenever a valid reference message is transmitted or received, the internal Ref_Mark is updated from the Sync_Mark. The difference between Ref_Mark and Sync_Mark is the Cycle Sync Mark (Cycle Sync Mark = Sync_Mark - Ref_Mark) stored in register **TTCSM**. The most significant 16 bits of the difference between Ref_Mark and the actual value of the local time is the cycle time (Cycle Time = Local Time - Ref_Mark).

Figure 682. Cycle Time and Global Time Synchronization

The cycle time that can be read from **TTCTC[CT]** is the difference of the node's local time and Ref_Mark, both synchronized into the Host clock domain and truncated to 16 bit. The global time exists for M_TTCAN Level 0 and Level 2 only, in Level 1 it is invalid. The node's view of the global time is the local image of the global time in (local) NTUs. After configuration, a potential time master will use its own local time as global time. The time master establishes its own local time as global time by transmitting its own Ref_Marks as Master_Ref_Marks in the reference message (bytes 3,4). The global time that can be read from **TTLGT[GT]** is the sum of the node's local time and its local offset, both synchronized into the Host clock domain and truncated to 16 bit. The fractional part is used for clock synchronization only.

A node that receives a reference message calculates its local offset to the global time by comparing its local Ref_Mark with the received Master_Ref_Mark (see in figure above). The node's view of the global time is local time + local offset. In a potential time master that has never received another time master's reference message, Local_Offset will be zero. When a node becomes the current time master after first having received other reference messages, Local_Offset will be frozen at its last value. In the time receiving nodes, Local_Offset may be subject to small adjustments, due to clock drift, when another node becomes time master, or when there is a global time discontinuity, signaled by **Disc_Bit** in the reference message. With the exception of global time discontinuity, the global time provided to the application program by register **TTLGT** is smoothed by a low-pass filtering to have a continuous monotonic value.

Figure 683. M_TTCAN Level 0 and Level 2 Drift Compensation

Figure 683 describes how in M_TTCAN Level 0,2 each time receiving node compensates the drift between its own local clock and the time master's clock by comparing the length of a basic cycle in local time and in global time. If there is a difference between the two values and the **Disc_Bit** in the reference message is not set, a new value for **TURNA[NAV]** is calculated. If the Synchronisation Deviation $SD = |NC - TURNA[NAV]| \leq SDL$ (Synchronisation Deviation Limit), the new value for **TURNA[NAV]** takes effect. Else the automatic drift compensation is suspended.

In M_TTCAN Level 0 and Level 2, **TTOST[QCS]** indicates whether the automatic drift compensation is active or suspended. In M_TTCAN Level 1, **TTOST[QCS]** is always '1'.

The current time master may synchronize its local clock speed and the global time phase to an external clock source. This is enabled by bit **TTOCF[EECS]**.

The stop watch function (see [Section 46.4.13, Stop watch](#)) may be used to measure the difference in clock speed between the local clock and the external clock. The local clock speed is adjusted by first writing the newly calculated Numerator Configuration Low to **TURCF[NCL]** (**TURCF[DC]** cannot be updated during operation). The new value takes effect by writing **TTOCN[ECS]** to '1'.

The global time phase is adjusted by first writing the phase offset into the TT Global Time Preset register **TTGTP**. The new value takes effect by writing **TTOCN[SGT]** to '1'. The first reference message transmitted after the global time phase adjustment will have the **Disc_Bit** set to '1'.

TTOST[QGTP] shows whether the node's global time is in phase with the time master's global time. **TTOST[QGTP]** is permanently '0' in M_TTCAN Level 1 and when the Synchronisation Deviation Limit is exceeded in M_TTCAN Level 0,2 (**TTOST[QCS]** = '0'). It is temporarily '0' while the global time is low-pass filtered to supply the application with a continuous monotonic value. There is no low-pass filtering when the last reference message contained a **Disc_Bit** = '1' or when **TTOST[QCS]**='0'.

46.4.15 M_TTCAN error level

The ISO 11898-4 specifies four levels of error severity:

- S0 - No Error
- S1 - Warning- Only notification of application, reaction application-specific.
- S2 Error- Notification of application. All transmissions in exclusive or arbitrating time windows are disabled (i.e. no data or remote frames may be started). Potential time masters still transmit reference messages with the Reference Trigger Offset **TTOST[RTO]** set to the maximum value of 127.
- S3 - Severe Error
Notification of application. All CAN bus operations are stopped, i.e. transmission of dominant bits is not allowed, and **CCCR[MON]** is set. The S3 error condition remains active until the application updates the configuration (set **CCCR[CCE]**).
If several errors are detected at the same time, the highest severity prevails. When an error is detected, the application is notified by **TTIR[ELC]**. The error level is monitored by **TTOST[EL]**.

The M_TTCAN signals the following error conditions as required by ISO 11898-4:

- Config_Error (S3)
Sets Error Level **TTOST[EL]** to "11" when a merged arbitrating time window is not properly closed or when there is a Tx_Trigger with a time mark beyond the Tx_Ref_Trigger.
- Watch_Trigger_Reached (S3)
Sets Error Level **TTOST[EL]** to "11" when a watch trigger was reached because the reference message is missing.
- Application_Watchdog (S3)
Sets Error Level **TTOST[EL]** to "11" when the application failed to serve the application watchdog. The application watchdog is configured via **TTOCF[AWL]**. It is served by reading register TTOST. When the watchdog is not served in time, bit **TTOST[AWE]** and interrupt flag **TTIR[AW]** are set, all M_TTCAN communication is stopped, and the M_TTCAN is set into bus monitoring mode (**CCCR[MON]** set to '1').
- CAN_Bus_Off (S3)
Entering **CAN_Bus_Off** state sets error level **TTOST[EL]** to "11". **CAN_Bus_Off** state is signaled by **PSR[BO]** = '1' and **CCCR[INIT]** = '1'.
- Scheduling_Error_2 (S2)
Sets Error Level **TTOST[EL]** to "10" if the MSC of one Tx_Trigger has reached 7. In addition interrupt flag **TTIR[SE2]** is set. The Error Level **TTOST[EL]** is reset to "00" at

the beginning of a matrix cycle when no Tx_Trigger has an MSC of 7 in the preceding matrix cycle.

- **Tx_Overflow (S2)**
Sets Error Level **TTOST[EL]** to “10” when the Tx count is equal or higher than the expected number of Tx_T triggers **TTMLM[ENTT]** and a Tx_Trigger event occurs. In addition interrupt flag **TTIR[TXO]** is set. The Error Level **TTOST[EL]** is reset to “00” when the Tx count is no more than **TTMLM[ENTT]** at the start of a new matrix cycle.
- **Scheduling_Error_1 (S1)**
Sets Error Level **TTOST[EL]** to “01” if within one matrix cycle the difference between the maximum MSC and the minimum MSC for all trigger memory elements (of exclusive time windows) is larger than 2, or if one of the MSCs of an exclusive Rx_Trigger has reached 7. In addition interrupt flag **TTIR[SE1]** is set. If within one matrix cycle none of these conditions is valid, the Error Level **TTOST[EL]** is reset to “00”.
- **Tx_Underflow (S1)**
Sets Error Level **TTOST[EL]** to “01” when the Tx count is less than the expected number of Tx_Triggers **TTMLM[ENTT]** at the start of a new matrix cycle. In addition interrupt flag **TTIR[TXU]** is set. The Error Level **TTOST[EL]** is reset to “00” when the Tx count is at least **TTMLM[ENTT]** at the start of a new matrix cycle.

46.4.16 M_TTCAN message handling

46.4.16.1 Reference message

For potential time masters the identifier of the reference message is configured via **TTRMC[RID]**. No dedicated Tx Buffer is required for transmission of the reference message. When a reference message is transmitted, the first data byte (M_TTCAN Level 1) resp. the first four data bytes (M_TTCANM_TTCAN Level 0 and Level 2) will be provided by the FSE. In case the Reference Message Payload Select **TTRMC[RMPS]** is set, the rest of the reference message's payload (Level 1: bytes 2-8, Level 0,2: bytes 5-6) is taken from Tx Buffer 0. In this case the data length **DLC** code from message buffer 0 is used.

Table 753. Number of Data Bytes transmitted with a Reference Messages

TTRMC.RMPS	TXBRP.TRP0	Level 0	Level 1	Level 2
0	0	4	1	4
0	1	4	1	4
1	0	4	1	4
1	1	4+MBO	1+MBO	4+MBO

To send additional payload with the reference message in Level 1 a **DLC > 1** has to be configured, for Level 0, 2 a **DLC > 4** is required. In addition the transmission request pending bit **TXBRP[TRP0]** of message buffer 0 must be set (see [Table 753](#)). In case bit **TXBRP[TRP0]** is not set when a reference message is started, the reference message is transmitted with the data bytes supplied by the FSE only.

For acceptance filtering of reference messages the Reference Identifier **TTRMC[RID]** is used.

46.4.16.2 Message reception

Message reception is done via the two Rx FIFOs in the same way as for event-driven CAN communication (see [Section 46.3.10, Rx handling](#)).

The Message Status Count MSC is part of the corresponding trigger memory element and has to be initialized to zero during configuration. It is updated while the M_TTCAN is in synchronization states In_Gap or In_Schedule. The update happens at the message's Rx_Trigger. At this point in time it is checked at which acceptance filter element the latest message received in this basic cycle had matched. The matching filter number is stored as the acceptance filter result. If this is the same the filter number as defined in this trigger memory element, the MSC is decremented by one. If the acceptance filter result is not the same filter number as defined for this filter element, or if the acceptance filter result is cleared, the MSC is incremented by one. At each Rx_Trigger and at each start of cycle, the last acceptance filter result is cleared.

The time mark of an Rx_Trigger should be set to a value where it is ensured that reception and acceptance filtering for the targeted message has completed. This has to take into consideration the RAM access time and the order of the filter list. It is recommended, that filters which are used for Rx_Triggers are placed at the beginning of the filter list. It is not recommended to use an Rx_Trigger for the reference message.

46.4.16.3 Message transmission

For time-triggered message transmission the M_TTCAN supplies 32 dedicated Tx buffers (see [Section 46.4.7.16, Dedicated Tx buffers](#)). A Tx FIFO or Tx queue is not available when the M_TTCAN is configured for time-triggered operation (**TTOCF[OM]** = "01" or "10"). Each Tx_Trigger in the trigger memory points to a particular Tx buffer containing a specific message. There may be more than one Tx_Trigger for a given Tx buffer if that Tx buffer contains a message that is to be transmitted more than once in a basic cycle or matrix cycle. The application program has to update the data regularly and on time, synchronized to the cycle time. The Host CPU is responsible that no partially updated messages are transmitted. To assure this the Host has to proceed in the following way:

Tx_Trigger_Single / Tx_Trigger_Merged / Tx_Trigger_Arbitration

- Check whether the previous transmission has completed by reading **TXBTO**
- Update the Tx buffer's configuration and/or payload
- Issue an Add Request to set the Tx Buffer Request Pending bit

Tx_Trigger_Continuous

- Issue a Cancellation Request to reset the Tx Buffer Request Pending bit
- Check whether the cancellation has finished by reading **TXBCF**
- Update Tx buffer's configuration and/or payload
- Issue an Add Request to set the Tx Buffer Request Pending bit

The message's **MSC** stored with the corresponding Tx_Trigger provides information on the success of the transmission. The **MSC** is incremented by one when the transmission could not be started because the CAN bus was not idle within the corresponding transmit enable window or when the message was started and could not be completed successfully. The **MSC** is decremented by one when the message was transmitted successfully or when the message could have been started within its transmit enable window but was not started because transmission was disabled (M_TTCAN in Error Level S2 or Host has disabled this particular message). The Tx buffers may be managed dynamically, i.e. several messages with different identifiers may share the same Tx buffer element. In this case the Host has to

assure that no transmission request is pending for the Tx buffer element to be reconfigured by checking **TXBRP**. If a Tx buffer with pending transmission request should be updated, the Host first has to issue a cancellation request and check whether the cancellation has completed by reading **TXBCF** before it starts updating.

The Tx Handler will transfer a message from the Message RAM to its intermediate output buffer at the trigger element which becomes active immediately before the Tx_Trigger element which defines the beginning of the transmit window. During and after the transfer time the transmit message may not be updated and its TXBRP bit may not be changed. To control this transfer time, an additional trigger element may be placed before the Tx_Trigger. This may be example of a Time_Base_Trigger which need not cause any other action. The difference in time marks between the Tx_Trigger and the preceding trigger has to be large enough to guarantee that the Tx Handler can read four words from the Message RAM even at high RAM access load from other modules.

46.4.16.3.1 Transmission in exclusive time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Single or Tx_Trigger_Continuous. There is no arbitration on the bus with messages from other nodes. The **MSC** is updated according the result of the transmission attempt. After successful transmission started by a Tx_Trigger_Single the respective Tx Buffer Request Pending bit is reset. After successful transmission started by a Tx_Trigger_Continuous the respective Tx Buffer Request Pending remains set. When the transmission was not successful due to disturbances, it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

46.4.16.3.2 Transmission in arbitrating time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Arbitration. Several nodes may start to transmit at the same time. In this case the message has to arbitrate with the messages from other nodes. The **MSC** is not updated. When the transmission was not successful (lost arbitration or disturbance), it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

46.4.16.3.3 Transmission in merged arbitrating time windows

The purpose of a merged arbitrating time window is, to enable multiple nodes to send a limited number of frames which are transmitted in immediate sequence, the order given by CAN arbitration. It is not intended for burst transmission by a single node. Since the node does not have exclusive access within this time window, it may happen that not all requested transmissions are successful.

Messages which have lost arbitration or were disturbed by an error, may be re-transmitted inside the same merged arbitrating time window. The re-transmission will not be started if the corresponding Transmission Request Pending flag was reset by a successful Tx cancellation. In single transmit windows, the Tx Handler transmits the message indicated by the message number of the trigger element. In merged arbitrating time windows, it can handle up to three message numbers from the trigger list. Their transmissions will be attempted in the sequence defined by the trigger list. If the time mark of a fourth message is reached before the first is transmitted (or cancelled by the Host), the fourth request will be ignored. The transmission inside a merged arbitrating time window is not time-triggered. The transmission of a message may start before its time mark, or after the time mark if the bus was not idle.

The messages transmitted by a specific node inside a merged arbitrating time window will be started in the order of their Tx_Triggers, so a message with low CAN priority may prevent the successful transmission of a following message with higher priority, if their is compelling bus traffic. This has to be considered for the configuration of the trigger list.

Time_Base_Triggers may be placed between consecutive Tx_Triggers to define the time until the data of the corresponding Tx Buffer needs to be updated.

46.4.17 M_TTCAN interrupt and error handling

The TT Interrupt Register **TTIR** consists off our segments. Each interrupt can be enabled separately by the corresponding bit in the TT Interrupt Enable register **TTIE**. The flags remain set until the Host clears them. A flag is cleared by writing a '1' to the corresponding bit position. The first segment consists of flags **CER**, **AW**, **WT**, and **IWT**. Each flag indicates a fatal error condition where the CAN communication is stopped. With the exception of **IWT**, these error conditions require a re-configuration of the M_TTCAN module before the communication can be restarted.

The second segment consists of flags **ELC**, **SE1**, **SE2**, **TXO**, **TXU**, and **GTE**. Each flag indicates an error condition where the CAN communication is disturbed. If they are caused by a transient failure, e.g. by disturbances on the CAN bus, they will be handled by the M_TTCAN protocol's failure handling and do not require intervention by the application program.

The third segment consists of flags **GTD**, **GTW**, **SWE**, **TTMI**, and **RTMI**. The first two flags are controlled by global time events (Level 0,2 only) that require a reaction by the application program. With a Stop Watch Event triggered by a rising edge on pin internal time values are captured. The Trigger Time Mark Interrupt notifies the application that a specific Time_Base_Trigger is reached. The Register Time Mark Interrupt signals that the time referenced by **TTOCN[TMC]** (Cycle, Local, or Global) equals time mark **TTTMK[TM]**. It can also be used to finish a Gap. The fourth segment consists of flags **SOG**, **CSM**, **SMC**, and **SBC**. These flags provide a means to synchronize the application program to the communication schedule.

46.4.18 Level 0

M_TTCAN Level 0 is not part of ISO11898-4. This operation mode makes the hardware, that in M_TTCAN Level 2 maintains the calibrated global time base, also available for event-driven CAN according to ISO11898-1. Level 0 operation is configured via **TTOCF[OM] = "11"**. In this mode the M_TTCAN operates in event driven CAN communication, there is no fixed schedule, the configuration of **TTOCF[GEN]** is ignored. External event-synchronized operation is not available in Level 0. A synchronized time base is maintained by transmission of reference messages. In Level 0 the trigger memory is not active and therefore needs not to be configured. The time mark interrupt flag (**TTIR[TTMI]**) is set when the cycle time has reached **TTOCF[IRTO] × 0x200**, it reminds the Host to set a transmission request for message buffer 0. The Watch_Trigger interrupt flag (**TTIR[WT]**) is set when the cycle time has reached 0xFF00. These values were chosen to have enough margin for a stable clock calibration. There are no further TT-error-checks. Register time mark interrupts (**TTIR[RTMI]**) are also possible. The reference message is configured as for Level 2 operation. Received reference messages are recognized by the identifier configured in register TTRMC. For the transmission of reference messages only message buffer 0 may be used. The node transmits reference messages any time the Host sets a transmission request for message buffer 0, there is no reference trigger offset.

Level 0 operation is configured via:

- TTRMC
- **TTOCF** except **EVTP**, **AWL**, **GEN**
- **TTMLM** except **ENTT**, **TXEW**
- TURCF

Level 0 operation is controlled via:

- **TTOCN** except **NIG**, **TMG**, **FGP**, **GCS**, **TTMIE**
- TTGTP
- TTTMK
- **TTIR** excluding bits **CER**, **AW**, **IWT SE2**, **SE1**, **TXO**, **TXU**, **SOG** (no function)
- **TTIR** the following bits have changed function
 - **TTMI** not defined by trigger memory - activated at cycle time **TTOCF[IRTO]** .
0x200
 - **WT** not defined by trigger memory - activated at cycle time 0xFF00

Level 0 operation is signaled via:

- TTOST excluding bits **AWE**, **WFE**, **GSI**, **GFI**, **RTO** (no function)

46.4.18.1 Synchronizing

[Figure 684](#) describes the states and state transitions in M_TTCAN Level 0 operation. Level 0 has no In_Gap state.

T0: transition condition always taking prevalence

T1: Init state left, cycle time is zero

T2: at least two successive reference messages observed (last reference message did not contain a set Disc_Bit or Next_is_Gap bit)

Figure 684. Level 0 schedule synchronization state machine

46.4.18.2 Handling of error levels

During Level 0 operation only the following error conditions may occur:

- Watch_Trigger_Reached (S3), reached cycle time 0xFF00
- CAN_Bus_Off (S3)

Since no S1 and S2 error are possible, the error level can only switch between S0 (No Error) and S3 (Severe Error). In M_TTCAN Level 0 an S3 error is handled differently. When error level S3 is reached, both **TTOST[SYS]** and **TTOST[MS]** are reset, and interrupt flags **TTIR[GTE]** and **TTIR[GTD]** are set.

When error level S3 (**TTOST[EL]** = "11") is entered, bus monitoring mode is, contrary to M_TTCAN Level 1 and Level 2, not entered. S3 error level is left automatically after transmission (time master) or reception (time slave) of the next reference message.

46.4.18.3 Master slave relation

[Figure 685](#) below describes the master slave relation in M_TTCAN Level 0. In case of an S3 error the M_TTCAN returns to state Master_Off.

Figure 685. Level 0 master to slave relation

46.4.19 Synchronization to external time schedule

This feature can be used to synchronize the phase of the M_TTCAN's schedule to an external schedule (e.g. that of a second M_TTCAN network or FlexRay network). It is applicable only when the M_TTCAN is current time master (**TTOST[MS]** = "11"). External synchronization is controlled by event trigger input pin. If bit **TTOCN[ESCN]** is set, a rising edge at event trigger pin the M_TTCAN compares its actual cycle time with the target phase value configured by **TTGTP[CTP]**. Before setting **TTOCN[ESCN]** the Host has to adapt the phases of the two time schedules e.g. by using the M_TTCAN gap control (see [Section 46.4.12, M_TTCAN gap control](#)). When the Host sets **TTOCN[ESCN]**, **TTOST[SPL]** is set.

If the difference between the cycle time and the target phase value **TTGTP[CTP]** at the rising edge at event trigger pin is greater than 9 NTU, the phase lock bit **TTOST[SPL]** is reset, and interrupt flag **TTIR[CSM]** is set. **TTOST[SPL]** is also reset (and **TTIR[CSM]** is set), when another node becomes time master. If both **TTOST[SPL]** and **TTOCN[ESCN]** are set, and if the difference between the cycle time and the target phase value **TTGTP[CTP]** at the rising edge at event trigger pin is less or equal 9 NTU, the phase lock bit **TTOST[SPL]** remains set, and the measured difference is used as reference trigger offset value to adjust the phase at the next transmitted reference message.

Note: The rising edge detection at event trigger pin is enabled with the start of each basic cycle. The first rising edge triggers the compare of the actual cycle time with TTGTP[CTP]. All further edges until the beginning of the next basic cycle are ignored.

46.5 CAN RAM arbiter

This block acts as a dynamic arbiter between the various CAN nodes and the CPU for granting access to the shared CAN memory. The dynamic arbitration ensures:

- 50% bandwidth for CPU, 50% shared by the CAN nodes when simultaneous access requested from all masters and CPU,
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access.

Note: From the arbiter prospective the CPU bandwidth may be limited to 50%. The CPU may be waiting stated due to this bandwidth limitation when accessing the shared memory.

46.5.1 Features

- Active low asynchronous reset
- 1–CPU + 5–CAN arbiter.
- Combined dynamic arbitration scheme: Bandwidth between CPU and M_CAN interfaces can be redistributed. If active, the CPU interface is granted a 50% portion of the available bandwidth.
- Bandwidth dynamic upgrading to requesting masters if other masters do not request access
- The SRAM access by a single master needs two cycles (address and data) for each read/write command. The arbiter has a pseudo address pre-fetching mechanism. This mechanism acts when multiple masters are accessing the SRAM and it overlaps the address cycle of one master with the data cycle of another master. In case of multiple masters accessing the SRAM, the pseudo address pre-fetching scheme saves multiple clock cycles.
- The peripheral GSI module enable acts as a request from each master. Each master will be made to wait at least one clock cycle before the grant is given. The arbiter ensures that the CPU does not wait for more than 1 clock cycle, hence ensuring a 50% guaranteed bandwidth.
- Time slot is defined as one peripheral clock cycle.

46.5.2 Functional overview using examples

The dynamic arbitration scheme is explained using the following examples.

- Example 1 (active CPU IF, 3 out of 3 CAN nodes are active):
 - CPU obtains every 2nd slot
 - CAN 1/2/3 obtains every 6th time slot
- Example 2 (inactive CPU IF, 4 out of 4 CAN nodes are active):
 - CPU obtains no time slots
 - CAN 1/2/3/4 obtains every 4th time slot
- Example 3 (active CPU IF, 2 out of 4 CAN node are active):
 - CPU obtains every 2nd time slot
 - Active CAN 1/2 obtains every 4th time slot
- Example 4 (inactive CPU IF, 2 out of 4 CAN node are active):
 - CPU obtains no time slots
 - Active CAN 1/2 obtains every 2nd time slot

46.6 SRAM interface and memory organization

The CAN subsystem will interface with an external RAM using this interface. The RAM sizes required for the CAN subsystem are summarized in the following sections.

46.6.1 Shared memory

The following table/s shows maximum possible configuration per Filter, FIFO and Buffer but not all of these items can be configured to maximum size at the same time due to the smaller implemented physical memory as listed in [Table 756](#).

Table 754. M_CAN message memory size

Memory element	Number of elements	32-bit word per element	Total 32-bit words
11-bit Filter	128	1	128
29-bit Filter	64	2	128
Rx FIFO 0	64	4	256
Rx FIFO 1	64	4	256
Rx Buffer	64	4	256
Tx Event FIFO	32	2	64
Tx Buffers	32	4	128
M_CAN message memory size (word)			1216

Please refer [Table 756](#) for the available physical memory space used in the device.

Table 755. M_TTCAN message memory size

Memory element	Number of elements	32-bit word per element	Total 32-bit words
11-bit Filter	128	1	128
29-bit Filter	64	2	128
Rx FIFO 0	64	4	256
Rx FIFO 1	64	4	256
Rx Buffer	64	4	256
Tx Event FIFO	32	2	64
Tx Buffers	32	4	128
Triggers	64	2	128
M_TTCAN message memory size (word)			1344

Please refer [Table 756](#) for the exact physical memory space used in the device.

46.6.2 ECC controller

The RAM embeds ECC logic and code to provide Single Error Correction / Double Error Detection (SECCDED). The module does not guarantee any proper functionality if more than 2 bits are in errors. It supports only 32-bit write access and 8-/16-/32-bit read access. The ECC error is reported to each CAN module as well as available at the CAN subsystem top, so that the same can be forwarded to the Error Management Module.

The module uses Hamming code for single error correction and double error detection logic. It involves transmitting data with multiple ecc_check bits and decoding the associated ecc_check bits when receiving data to detect errors. The SECCDED Hamming code is not able to detect three bit errors. Rather, in the presence of a three bit error, a conventional SECCDED code returns an error code that is indistinguishable from an error code resulting from a single bit error. Hence, this module does not guarantee any proper functionality when more than 2-bits are in error.

The ecc_check bits are parallel parity bits generated from XORing certain bits in the original data word. If bit error(s) are introduced in the codeword, several ecc_check bits show parity errors after decoding the retrieved codeword. The combination of these ecc_check bit errors display the nature of the error. In addition, the position of any single bit error is identified from the ecc_check bits.

The ECC error address is reported at the top of the subsystem using a 16 bit ECC error address signal. This address is valid only when the ECC bit error output is valid.

46.6.2.1 Features

The ECC module supports the following:

- `ecc_error = 00` ' No error is detected in the read data from memory
- `ecc_error = 01` ' This indicates single bit error occurred within the 39-bit codeword. In addition, the error is corrected, and the forwarded data to the master is error free.
- `ecc_error = 10` ' This indicates that a two bit error has occurred within the codeword. In this case, no error correction is possible.
- `ecc_error = 11` ' This indicates that errors beyond the detection capability have occurred within the codeword and no error correction is possible. This is an invalid error type.

46.6.3 Transmit message buffer locking mechanism

Note: Please refer to Device Configuration chapter to see the number of CAN nodes used in the device.

This block will implement a transmit message buffer locking mechanism and trigger memory elements when the M_TTCAN is outside the INIT state using the CAN nodes internal flags output.

The Host controller has to access the Message RAM for updating transmit message buffers (e.g. the data section), the M_CAN controller needs access to the Message RAM to execute acceptance and transmit filtering in time and to prepare the next message for transmission by transferring it to the CAN core.

To avoid message buffer corruption, further host accesses to message buffers which are requested for transmission should be prevented. Otherwise, if the Host updates a message buffer which is simultaneously transferred to the CAN core, inconsistent data may be transmitted on the CAN bus.

This functionality is achieved using the “transmit buffer request pending” (M_CAN) and “configuration change enable” (M_TTCAN) information of the CAN modules. With the information from these signals, the message buffer locker prevents Host accesses from transmitting message buffers which are requested and pending for transmission and trigger memory elements when the M_TTCAN is outside the INIT state.

46.6.3.1 Transmit message buffer access locking for both M-CAN and TT-CAN

Each CAN module can have at most 32 TX Buffers and the size of each TX Buffer is 4 words. The CPU write locking mechanism ensures that whenever any TX Buffer's pending request is set (by the TRP bit of the TXBRP register), the CPU does not get any write access to the corresponding TX buffers. If the CPU tries to write into a TX Buffer whose pending request is set it receives an error response on the CAN RAM Transfer Error port.

46.6.3.2 Trigger memory element access locking for TT-CAN

Up to 64 trigger memory elements can be configured in a TT-CAN Module and the size of each trigger memory element is 2 words. The trigger memory elements have to be written when the TT-CAN is in INIT state. Write access to the trigger memory elements outside INIT state is not allowed. The CPU write locking mechanism ensures that whenever the TT-CAN is not in the INIT state (CCE bit of the CCCR register is set to '0'), the CPU does not get any write access to the Trigger Memory Elements. If the CPU tries to write into a TX Buffer, while the TT-CAN is not in the INIT state, it will get an error response on the CAN RAM Transfer Error.

46.7 Time Triggered CAN matrix and basic cycles management

The following figure shows hardware control for M_TTCAN cycles management.

Note 1: Multiplexers and control logic is implemented in the SIUL block. See SIUL Multiplexed Signal Configuration Register (SIUL2: MSCR 753, MSCR 754).

Note 2: For the signal details from various blocks see section SIUL Module-port MSCR assignments and SSS values (SIUL2: MSCR 753, MSCR 754).

Note 3: See device configuration chapter for the availability of the STM instances.

Figure 686. Hardware control for M_TTCAN cycles management

46.8 CAN nodes 1 and 2 I/Os sharing

Each CAN node has its Tx/Rx signals connected to separated GPIO pairs. It is required for M_CAN_1 and M_CAN_2 to share one common GPIO pair. This feature is described below.

Figure 687. M_CAN_1 and M_CAN_2 connections to GP I/Os

46.9 External signal description

The CAN subsystem has following external pins.

- M_CAN_x_RX: M_CAN x receive input
- M_CAN_x_TX: M_CAN x transmit output
- M_TTCAN_x_RX: M_TTCAN x receive input
- M_TTCAN_x_TX: M_TTCAN x transmit output

46.10 Memory map and register description

46.10.1 Shared memory map

[Table 756](#) shows the shared memory map vs CAN subsystem transmit, receive and filters elements.

Table 756. Shared memory map vs CAN transmit, receive and filters elements

Start Address Offset (byte)	End Address Offset (byte)	CAN block/sub block		Comment
0x0000	0x0CFF	M_CAN1	Standard Filters	This available physical memory space could be configured for Filters/ FIFO/Buffer according to Table 754 .
			Extended Filters	
			Rx FIFO 0	
			Rx FIFO 1	
			Rx Buffer	
			Tx Event FIFO

			Rx FIFO 0	
			Rx FIFO 1	
			Rx Buffer	
			Tx Event FIFO	
0x3C00	0x3DFF		Tx Buffers	Protected from CPU write access using the M_CAN3 TXBRP register output

Note: There is no write access protection from a CAN module to the message memory space. The write access protection is only for CPU access to the message memory.

Note: The start address for every memory section is to be configured by the user in the relevant CAN modules registers. However there is no hardware check in the RAM interface for the start address consistency.

However the number of filters, Tx/Rx buffers, triggers used, it is mandatory for the user to configure the start address registers, specified in [Table 757](#), in order to fit the memory mapping specified in [Table 756](#).

Note: The CPU uses the peripheral interface to access the memory locations. It must be noted that there is no transfer error reported to the CPU in case of access to reserved memory locations.

47 Serial Interprocessor Interface (SIPI)

47.1 Introduction

The Serial Interprocessor Interface (SIPI) is an application layer protocol that runs on top of the LFAST module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

47.1.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multimaster, multi-channel memory interface between two devices using few interconnecting signals. But the protocol is designed in such a way that a subset of the protocol can be implemented, where die area is more important than features.

Main scalable features:

- Number of concurrent channels:
 - Full Implementation = 4
 - Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum Implementation either Initiator or Target
- Full Implementation includes a block transfer feature, but this feature is optional.

The rest of this section describes a full implementation of SIPI, which includes: an Advanced High-Performance Bus (AHB-Lite) master interface, Direct Memory Access (DMA) interface, LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS).

47.2 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

47.3 SIPI block diagram

1. Finite State Machine

Figure 690. SIPI block diagram

47.4 Feature description

This section describes the features of the SIPI module.

47.4.1 Main Features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability
- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface that is used by target node to access shared memory
- Target node contains a set of nine 32-bit internal registers to store commands
- Up to two outstanding requests are supported at initiator.

47.4.2 Standard features

- IPS bus interface
- SPP DMA2x bus interface
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

47.5 Functional description

47.5.1 External signals

The SIPI has no chip external signals.

47.5.2 Frame format

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

47.5.2.1 Register read request

Figure 691. SIPI register read request

47.5.2.2 Register read response, ID request response

Figure 692. SIPI read response

47.5.2.3 Register write request

Figure 693. SIPI register write request

47.5.2.4 Trigger transfer, ID transfer, write acknowledge and streaming write acknowledge

Figure 694. SIPI write acknowledge

47.5.2.5 Streaming write request

Figure 695. Streaming write request format^{(1),(2)}

- 1. Direct write operations are used to set the streaming address.
- 2. Streaming data write is performed using the format shown in [Figure 695](#).

47.5.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

47.5.2.6.1 SIPI header coding

[Figure 696](#) shows the SIPI header coding.

Figure 696. SIPI header coding

[Table 758](#) shows the command coding for the bits[12:8] of the header.

Table 758. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
00	Read 8 bits	64
01	Read 16 bits	64
02	Read 32 Bits	64
03	Reserved	—
04	Write 8 bits with ACK	96
05	Write 16 bits with ACK	96
06	Write 32 bits with ACK	96

Table 758. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
07	Reserved	—
08	ACK – OK	32
09	ACK – Fault	32
0A	Read Answer – OK	64
0B	Reserved	—
0C	Trigger comm and with ACK	32
0D	Reserved	—
...	...	...
11	Reserved	—
12	ID Register Read Request	32
13	Reserved	—
...	...	...
16	Reserved	—
17	Stream Data with ACK (32 bytes)	288
18	Reserved	—
...	...	...
1F	Reserved	—

Figure 697 shows the contents of bits[7:0] in the SIPI header.

Figure 697. SIPI header channel field

Table 759 shows the channel number coding.

Table 759. SIPI Header Channel Number Coding

SIPI Channel Name	Channel Number Coding in header(s)		Comment
	SIPI Channel Coding Select Bit		
	Code Table I (1)	Code Table II (0)	
0 (Channel A)	000b	100b	In use
1 (Channel B)	001b	101b	In use

Table 759. SIPI Header Channel Number Coding

SIPI Channel Name	Channel Number Coding in header(s)		Comment
	SIPI Channel Coding Select Bit		
	Code Table I (1)	Code Table II (0)	
2 (Channel C)	010b	110b	In use
3 (Channel D)	011b	111b	In use
4 (Channel E)	100b	000b	Reserved
5 (Channel F)	101b	001b	Reserved
6 (Channel G)	110b	010b	Reserved
7 (Channel H)	111b	011b	Reserved

47.5.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

47.5.2.8 Payload field

[Table 760](#) shows the payload sizes of the LFAST frame.

Table 760. Payload size of LFAST channel frame

LFAST Code (bin)	SIPI Code (bin)	LFAST Payload Size (bits)	(bytes)
000	—	8	1
001	—	32	4
010	010	64	8
011	011	96	12
100	100	128	16
101	101	256	32
110	110	512	64
111	111	288	36

[Table 761](#) shows the converted coding of LFAST for a given SIPI code.

Table 761. Converted coding of LFAST channel code for SIPI headers

LFAST Code (bin)	SIPI Code (bin)	Channel (hex) ⁽¹⁾
0100	100	A
0101	101	B
0110	110	C
0111	111	D

Table 761. Converted coding of LFAST channel code for SIPI headers (continued)

LFAST Code (bin)	SIPI Code (bin)	Channel (hex)⁽¹⁾
1000	000	E (not used by SIPI)
1001	001	F (not used by SIPI)
1010	010	G (not used by SIPI)
1011	011	H (not used by SIPI)

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
 SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
 SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
 SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

47.5.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome ($x^{16} + x^{12} + x^5 + 1$). The data stream is transmitted with the MSB sent first.

47.5.2.9.1 CRC examples

47.5.2.9.1.1 Example 1 – 32-bit write on channel 1 with ID1

- Header = 260Ah
- Address = 1122_3344h
- Data = CCDD_EEFFh
- CRC = BF7Dh

47.5.2.9.1.2 Example 2 – 32-bit read on channel 2 with ID2

- Header = 420Ch
- Address = 89AB_CDEFh
- CRC = 6B80h

47.5.2.9.1.3 Example 3 – Event command on channel 3 with ID3

- Header = 6C0Eh
- CRC = B286h

47.6 Transfer types

This section describes the available transfer types of the SIPI module.

47.6.1 Read transfer

A Read transfer can be of two types:

- Read request transfer (at initiator node)
- Read response transfer (at target node)

47.6.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in [Figure 698](#).

Figure 698. Read request transfer

47.6.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see [Figure 699](#)). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see [Figure 700](#)).

Figure 699. Read answer transfer

**Figure 700. Data allocation**

Note: In case of 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
 Bits[1:0]
 00 - byte 3 enabled (MSB)
 01 - byte 2 enabled
 10 - byte 1 enabled
 11 - byte 0 enabled (LSB)

In case of 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
 Bit[0]
 0 - half-word 1 enabled (MSB)
 1 - half-word 0 enabled (LSB)

47.6.3 Register write transfer

Register Write transfer can be of two types:

- Normal write transfer - channels 0, 1, 2 and 3
- Streaming data transfer - channel 2 only

Register Write transfer can be done through a normal write transfer - channels 0, 1, 2 and 3 as shown in [Figure 701](#).

Figure 701. Register write transfer

47.6.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and 16-bit CRC as shown in [Figure 702](#).

Figure 702. Write transfer

Note: In the case of an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as a byte enable.

- Bits[1:0]:
- 00 – byte 3 enabled (MSB)
- 01 – byte 2 enabled
- 10 – byte 1 enabled
- 11 – byte 0 enabled (LSB)

In the case of a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as a half-word enable.

- Bit[0]:
- 0 – half-word 1 enabled (MSB)
- 1 – half-word 0 enabled (LSB)

47.6.3.2 Streaming write transfer

Streaming write transfers have 256 bits of payload.

47.6.3.2.1 Streaming write transfer with address

Setting the address is performed using a direct write transfer. MAXCR and SIPIARR are written before the SIPIACR. This is to ensure that the unwanted behavior of the SIPI trying to access non-shared memory is avoided. This is only true for the very first streaming command, subsequent streaming command(s) may not have the need to write MAXCR and SIPIARR.

47.6.3.2.2 Streaming transfer with data

[Figure 703](#) shows the packet structure of streaming transfers that contain data.

Figure 703. Streaming transfer with data

47.6.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see [Figure 704](#)). The CRC bits are calculated on the header field.

Figure 704. Write Acknowledge transfer

47.6.5 ID request response

47.6.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in [Figure 705](#).

Figure 705. ID request transfer

47.6.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in [Figure 706](#).

Figure 706. ID request response transfer

Note: The ID request response contains the value of the CHIP ID in place of data.

47.7 Transfer API and flow charts

Figure 707. SIPI single register write API

*Note: TC = Transmit Command

For a single Write Transfer Request generation (*Figure 707*):

1. Configure data and CCR n at the initiator node.
2. Configure CAR n at the initiator node.

As soon as the channel address register (CAR n) is written and if CCR n [CHEN] = 1, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.

3. Software polls the status register bits (CSR n) to determine when the request completes, CSR n [ACKR] = 1. An interrupt will be generated if the corresponding CIR n [ACKIE] = 1.

On a single Write transfer request reception (*Figure 708*):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process is completed, the target node will generate an acknowledge frame and send it back to the LFAST.

Figure 708. SIPI Single Register Write API – Flow Chart

Figure 709. SIPI Multiple Register Write API

For Multiple Write Transfer Request generation ([Figure 709](#)):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write $CCR_n[CHEN] = 1$ and $CCR_n[DAN] = 1$.
3. SIPI will generate `ipd_req` and send it to the DMA controller.
4. SIPI will start copying data into the CDR_n through its DMA interface, depending on the transfer count and data registers size. $CDR2[0]$ should be written with the MSB.
5. When the copying process is complete, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST.
6. Software should poll the CSR_n status register bits to determine if the request has completed. If $CSR_n[ACKR] = 1$, an interrupt will be generated (if the corresponding $CIR_n[ACKIE] = 1$).
7. If $CCR_n[DEN] = 1$, the SIPI request will transfer to the DMA controller. If not, the `ipd_req` will not be sent and the state machine goes idle.
8. Steps 4–7 will be repeated.

On Multiple Write transfer request reception ([Figure 709](#)):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process is completed, target node will generate an acknowledge frame and send it back to the LFAST.

Figure 710. SIPI Single Register Read API

For Single Read Transfer Request generation ([Figure 710](#)):

1. Software/DMA will configure $CCRn$ and $CDRn$, with the last step by writing $CARn$.
2. As soon as CAR is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll $CSRn$ to determine when the request has completed. If $CSRn[RAR] = 1$, and interrupt will be generated (if $CIRn[RAIE] = 1$). If $CSRn[RAR]$ does not set then $SIPERR[TOEn] = 1$, which indicates a timeout has occurred.
4. If $CSRn[RAR] = 1$, then software can read the data register, or can take other necessary action if $CSRn[RAR] = 0$.

On Single Read transfer request reception ([Figure 710](#)):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process is completed, target node will send read response back to LFAST.

Figure 711. SIPI multiple register read API

For multiple read transfer request generation ([Figure 711](#)):

1. Software/DMA will configure $CCRn$ and $CDRn$, with the last step by writing $CARn$.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then start transmitting data to the LFAST.
3. Software should poll $CSRn$ to determine when the request has completed. If $CSRn[RAR] = 1$ and $CIRn[RAIE] = 1$, an interrupt will be generated. If $CSRn[RAR]$ does not set, then $SIPERR[TOEn] = 1$, which indicates a timeout.
4. Steps 2–3 will be repeated for multiple requests.

On Multiple Read transfer request reception ([Figure 711](#)):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

[Figure 712](#), [Figure 713](#), [Figure 714](#) and [Figure 715](#) show the SIPI data streaming of data.

Figure 712. SIPI data stream model

Figure 713. SIPI data stream model - Initiator

Figure 714. SIPI data stream model - Target

Figure 715. SIPI data stream with acknowledge trigger

47.8 DMA programming sequence

1. Software configures TCD (DMA data).
2. [BLG_SIPI_0004][Covers: ADD20.243]DMA transfers from RAM to SIPI registers.[end]
3. [BLG_SIPI_0005][Covers: ADD20.243]SIPI starts transferring the data through LFAST Tx ports.[end]
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. If SIPI has received a read response, and error flags are not set on the LFAST Rx port, SIPI will assert a request. In case of an error, move to Step ⁽⁸⁾.
6. As soon as the request is asserted, DMA transfer starts between the SIPI registers and RAM.
7. If DMA transfer minor loop/major loop is complete, the request is negated.
8. If an error occurs:
 - The SIPI generates an interrupt
 - Software takes control of the SIPI
9. Steps ⁽⁵⁾–⁽⁸⁾ are repeated until the transfer is finished.

47.9 Modes of operation

SIPI has three operating modes: Initialization, Normal and Module Disable modes. After hardware reset the SIPI is in module disable mode, which helps reduce power consumption.

47.9.1 Initialization mode (INIT)

To enter INIT mode software writes SIPIMCR[INIT] = 1 (SIPIMCR[MOEN] = 1 must be written before attempting to write SIPIMCR[INIT]). To exit initialization mode software writes SIPIMCR[INIT] = 0.

When in initialization mode, all message transfers are stopped. If software invokes initialization mode when a bus transfer is in progress, the transfer will be aborted immediately whether the transfer has completed, or not.

Note: It is recommended that software checks the SIPI state (SIPIMCR[MOEN]) before setting SIPIMCR[INIT].

47.9.2 Normal mode (NM)

Once software has completed initialization of SIPI (SIPIMCR[INIT] = 1), it can enter Normal mode by writing SIPIMCR[INIT] = 0. SIPI needs to be in Normal mode for all data transfers.

Note: .SIPI must be enabled before attempting to write to SIPIMCR[INIT] (for example, SIPIMCR[MOEN] = 1).

47.9.3 Module disable (MD)

Module Disable mode in the SIPI is used to help reduce power consumption. By default, SIPI is in disable mode, SIPIMCR[MOEN] = 0, and is exited by writing SIPIMCR[MOEN] = 1. All the activities on the SIPI Tx and Rx ports are immediately stopped in Module Disable mode.

47.10 Errors

This section describes the potential errors that can occur during SIPI operation.

47.10.1 Timeout error

This error is generated at the initiator node when the acknowledge/response is not received within the configured time in the corresponding $CTORn[TOR]$ field setting. $SIPERR[TOEn] = 1$ indicates that a channel timeout error has occurred.

Note: SIPI should not drop the response even after timeout occurs. Software polls both error and status flags after the transfer to see if there was a timeout error. If there was a timeout error the response received may be discarded.

47.10.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match with the calculated CRC. When a CRC error is detected the $SIPISR[GCRCE]$ is set and an interrupt will be generated if $SIPIMCR[CRCIE] = 1$.

Note: In the case of a CRC error, the target node will not send an acknowledge to the initiator node. Then an interrupt will be generated on the target side if the corresponding interrupt enable bit is set. The initiator node will detect a time-out and take necessary action.

47.10.3 Maximum count reached error

This error is always generated at the target node only. The maximum count reached error is generated when the value of the $SIPACR$ equals $MAXCR$ (see [Section 47.14.1.12, SIPI Address Count Register \(SIPACR\)](#) and [Section 47.14.1.10, Max Count Register \(MAXCR\)](#) for more details). The $SIPISR[MCR]$ will be set, and an interrupt will be generated if $SIPIMCR[MCRIE] = 1$.

47.10.4 TID error

This error is always generated at the initiator node only. It is generated when header bits 15–13 do not match $CSRn[TID]$ (transaction ID bits), (see [Section 47.14.1.2, Channel Status Register \(CSRn\)](#)). The $CSRn[TIDE]$ bit will be set when a TID error is detected, and an interrupt will be generated if $CIRn[TIDIE] = 1$.

47.10.5 Acknowledge error

When an incorrect Acknowledge is received the $SIPERR[ACKRn]$ will be set, at the initiator node only, and an interrupt will be generated if $CIRn[WAIE] = 1$.

47.11 CRC calculation

Example: If header is AAB Bh, address is 1122_3344h and data is CCDD_EEFFh. Then CRC calculation will take place as follows:

- 1) The CRC seed is initialized by FFFF_FFFFh.
- 2) All the data will be mirrored before sending to CRC IP (for example, MSB will be sent as LSB).

3) So the header will be sent as DD55_0000h.

4) Address will be sent as 22CC_4488h.

5) Data will be sent as FF77_BB33h.

Note: Please refer to the Cyclic Redundancy Check Unit (CRC) chapter in this manual for a detailed description of CRC generation and operation.

47.12 Interrupt logic

A description of the interrupt logic can be found in [Figure 716](#)

Figure 716. Interrupt description

47.13 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

Figure 717. SIPI control & status overview – Register transfer

47.14 Memory map and register description

47.14.1 Register descriptions

47.14.1.1 Channel Control Register (CCRn)

Note: Back to back transactions are not supported on a single channel (for example, if the channel busy bit, $CSRn[CB] = 1$, is configured for 1 channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, $CSRn[CB] = 0$).

PRIORITY SCHEDULING: The channel whose $CARn$ is written first will have access first, irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Priority scheduling occurs when the LFAST is unable to receive data, and no channel is pending transmission. The reason for the scheduling is that a common CRC module is shared by all channels.

Note: This register can only be written during Initialization mode ($MCR[INIT] = 1$), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted ($CSRn[CB] = 1$, [Section 47.14.1.2, Channel Status Register \(CSRn\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding $CARn$ ([Section 47.14.1.6, Channel Address Register \(CARn\)](#)).

Figure 718. Channel Control Register (CCRn)

1. The order of priority for writing to IDT, WRT and RRT must be in this order: 1) IDT, 2) RRT, 3) WRT.
2. Only transfers with channel 2 can write 1 to this bit. All other channels forces $CCRn[ST] = 0$. The $CCR2[WRT]$ and $CCR2[ST]$ bits must be set for streaming.

Table 763. CCR*n* field descriptions

Field	Description
0–14	Reserved
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in the CAR. 0 Trigger command not sent 1 Trigger command sent
16–23	Reserved
24–25 WL[1:0]	Word Length Transfer. For Streaming write WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all the channel enables are enabled simultaneously, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0 for channels 0, 1 and 3. It can only be written for channel 2 (CCR2). This bit can only be written when CCR <i>n</i> [WRT] = 1. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. 0 Read request will not be sent 1 Read request transfer by the initiator. This bit cannot be written if CCR <i>n</i> [IDT] = 1.
30 WRT	Write Request Transfer. 0 No write request will be sent 1 Write request transfer by the initiator. This bit cannot be written if CCR <i>n</i> [IDT] = 1 or CCR <i>n</i> [RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after 1 major loop has completed. 0 Channel will be used for bus interface access 1 Channel will be used for DMA access

47.14.1.2 Channel Status Register (CSR*n*)

The CSR*n* contains the status bits for the current transfer.

1. Field can only be written during Initialization mode (MCR[INIT] = 1).

Table 766. CTORn field descriptions

Field	Description
0–23	Reserved
24–31 TOR	Timeout value for transmitted requests. These bits can only be written by software in initialization mode, SIPIMCR[INIT] = 1. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPIMCR[PRSCLR].

47.14.1.5 Channel CRC Register (CCRCn)

CCRCn is read-only register that returns the CRC calculated value on the header, address, and data bits.

Figure 722. Channel CRC Register (CCRCn)

Table 767. CCRCn field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

47.14.1.6 Channel Address Register (CARn)

The CAR contains the data transmission target address. For streaming operations this register contains the start address. The CARn is a 32-bit register and can be written anytime by software or DMA.

Figure 723. Channel address Register (CAR_n)

1. This register holds the start address of streaming operations.

Table 768. CAR_n field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

47.14.1.7 Channel Data Register (CDR_n)

The CDR_n contains the data to be transmitted, and can be written anytime by software or DMA. The data can be written in 8, 16 or 32 bit formats.

Figure 724. Channel Data Register (CDR_n)

Table 769. CDR_n field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

Table 770. Channel data Register address offsets

Register	Address Offset (hex)
CDR0	001Ch
CDR1	003Ch
CDR2[0]–CDR2[7]	005Ch, 0060h, 0064h, 0068h, 006Ch, 0070h, 0074h, 0078h
CDR3	0098h

47.14.1.8 SIPI Module Configuration Register (SIPIMCR)

The SIPIMCR is a 32-bit global configuration register of the SIPI.

Figure 725. SIPI Module Configuration Register (SIPIMCR)

Offset: 009Ch												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FRZ		HALT	0	0	PRSCLR ⁽¹⁾										
W		0														
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	AID ⁽¹⁾		0	0	0	CRCIE ⁽²⁾	MCRIE ⁽²⁾	0	0	0	0	CHNSB ³	TEN ⁽²⁾	INIT ⁽²⁾	MOEN	SR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Register bit can be read/cleared by software. Can be written in initialization mode only (SIPIMCR[INIT] = 1).

2. Can only be written when SIPIMCR[MOEN] = 1.

3. Can be written only once after reset.

Table 771. SIPIMCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
1	Reserved
2 HALT	Halt Mode Enable. Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. 0 No Freeze mode request 1 Enters Freeze mode if FRZ bit is asserted.
3–4	Reserved
5–15 PRSCLR	These bits should be programmed by software in initialization mode, SIPIMCR[INIT] = 1, writes during other times are ignored. The timeout counter runs on the prescaled system clock. Default value is 64 (040h). The allowed programmable values are: 040h 64 080h 128 100h 256 200h 512 400h 1024
16–17 AID	Address Increment/Decrement. These bits define the type of address change at the target node. 00 no change. address stays same 01 address increments by 4 10 address decrements by 4. 11 Reserved
18–20	Reserved
21 CRCIE	CRC Error Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
22 MCRIE	Max Count Reached Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
23–26	Reserved
27 CHNSB	Channel coding select bit 0, 1 : Channel number select as per Table 759, SIPI Header Channel Number Coding .
28 TEN	Target Enable. Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in “streaming without ACK” mode. This bit has to be enabled for transmission operations as well.
29 INIT	Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPIMCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits cannot be enabled together. 0 Normal Mode 1 Initialization Mode

Table 771. SIPIMCR field descriptions (continued)

Field	Description
30 MOEN	Module Enable. This bit should be set or cleared by software. When this bit is negated, all SIPI operations are immediately stopped.
31 SR	Soft Reset. Setting this bit clears all status and error registers and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.

47.14.1.9 SIPI Status Register (SIPI SR)

The SIPI SR is the global status register of SIPI.

Figure 726. SIPI Status Register (SIPI SR)

Offset: 00A0h

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 772. SIPI SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. 0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge This read-only bit indicates that SIPI is in Disable Mode. Either of these low power modes cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI not in any low power modes 1 SIPI is either in Disable Mode
2–20	Reserved

Table 772. SIPI SR field descriptions (continued)

Field	Description
21 GCRCE	Global CRC Error Bit 0 No CRC error 1 CRC error occurred
22 MCR	Maximum Count Reached. This bit will be set whenever SIPIACR[ADCNT] = MAXCR[MXCNT]. An interrupt will be generated when this bit is set only if SIPIMCR[MCRIE] = 1. This bit should be cleared by software.
23	Reserved
24–27 TE	Trigger Event on Respective Channels. This field enables interrupts for target nodes. TE3 = 1 - Channel 3 trigger event TE2 = 1 - Channel 2 trigger event TE1 = 1 - Channel 1 trigger event TE0 = 1 - Channel 0 trigger event
28–31 STATE	These bits reflect the transmit state machine status. They can be polled for determination of state machine status. 0000 IDLE 0001 HEADER_AND_ADDRESS_FIELD 0010 HEADER_AND_DATA_FIELD 0011 HEADER_AND_CRC_FIELD 0100 ADDRESS_AND_CRC_FIELD 0101 ADDRESS_AND_DATA_FIELD 0110 DATA_AND_CRC_FIELD 0111 DATA_FIELD

47.14.1.10 Max Count Register (MAXCR)

The MAXCR contains the maximum address count value at target node. It is programmed via direct write request through the initiator. This register can be read or written by software anytime.

Figure 727. Max Count Register (MAXCR)

Table 773. MAXCR field descriptions

Field	Description
0–29 MXCNT	This register contains the maximum address count value at target node. It should be programmed via direct write request through initiator.
30–31	Reserved

47.14.1.11 SIPI Address Reload Register (SIPIARR)

The SIPIARR contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator. This register can be read or written anytime.

Figure 728. SIPI Address Reload Register (SIPIARR)

Offset: 00A8h

Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 774. SIPIARR field descriptions

Field	Description
0–29 ADRLD	Contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.
30–31	Reserved

47.14.1.12 SIPI Address Count Register (SIPIACR)

This register reflects the count value of address counter at target node. It should be configured by direct write request from initiator. This register can be read/written by software anytime.

Figure 729. SIPI Address Count Register (SIPIACR)

Table 775. SIPIACR field descriptions

Field	Description
0–29 ADCNT	Reflects the count value of address counter at target node. It should be configured by direct write request from the initiator. This register can be read/written by software anytime. At the end of the streaming operation, SIPIACR will point to the next address to be written.
30-31	Reserved

Note: *SIPIARR, SIPIACR and MAXCR will be configured by direct write operation through the initiator.*

[BLG_SIP_0003][Covers: ADD20.244] When a streaming write command is received, the target will start the write operation from the address present in SIPIACR. [end]

[BLG_SIP_0007][Covers: ADD20.244] After each 32-bit write has completed, SIPIACR[ADCNT] is compared against MAXCR[MXCNT]. If they are equal, SIPIACR[ADCNT] is loaded with the value stored in SIPIARR[ADRLD]. If they are not equal, the SIPIACR[ADCNT] will increment by 4, decrement by 4, or remain the same (depending on configuration). In either case, the SIPIACR[ADCNT] will contain the address at which the next streaming write will occur. [end]

47.14.1.13 SIPI Channel Error Register (SIPIERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate communication errors.

Figure 730. SIPI Channel Error Register (SIPIERR)

31 ACKE0	Acknowledge Error for Channel 0. 0 Acknowledge received is correct. 1 Acknowledge received is not correct.

48 Deserial Serial Peripheral Interface (DSPI)

48.1 Introduction

The Deserial Serial Peripheral Interface (DSPI) module provides a synchronous serial bus for communication between an MCU and an external peripheral device. The module supports MCU pin count reduction through serialization and deserialization of MCU internal signals transmitted over the SPI serial link.

Note: For the chip-specific implementation details of this module's instances, see the *Device Configuration* chapter.

48.1.1 Block diagram

Figure 731 provides the block diagram of this module.

Figure 731. DSPI block diagram

48.1.2 Features

The DSPI supports these features:

- full-duplex, four-wire synchronous transfers
- Master and Slave modes: data streaming operation in slave mode with continuous slave selection
- buffered transmit operation using the TX FIFO with depth of 4 entries
- buffered receive operation using the RX FIFO with depth of 4 entries
- asynchronous clocking scheme for Register and Protocol interfaces
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- visibility into TX and RX FIFOs for ease of debugging
- programmable transfer attributes on a per-frame basis:
 - 8 transfer attribute registers along with 8 extended transfer attribute registers
 - serial clock with programmable polarity and phase
 - various programmable delays
 - programmable serial frame size of 4 to 64 bits, expandable by software control: SPI frames longer than 32 bits can be supported using the continuous selection format
 - continuously held chip select capability
 - parity control
- 8 Peripheral Chip Selects, expandable to 256 with external demultiplexer
- deglitching support for up to 128 Peripheral Chip Selects with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
 - TX FIFO is not full (TFFF)
 - RX FIFO is not empty (RFDF)
 - CMD FIFO is not full (CMDFFF)
- interrupt conditions:
 - End Of Queue reached (EOQF)
 - TX FIFO is not full (TFFF)
 - CMD FIFO is not full (CMDFFF)
 - Transfer of current frame Complete (TCF)
 - Transfers due from current Command frame Complete (CMDTCF)
 - Transfer of current SPI frame Complete (SPITCF)
 - attempt to transmit with an empty Transmit FIFO (TFUF)
 - RX FIFO is not empty (RFDF)
 - frame received while Receive FIFO is full (RFOF)
 - SPI Parity Error (SPEF)
 - data present in TX FIFO while CMD FIFO is empty (TFIWF)
- global interrupt request line
- modified SPI transfer formats for communication with slower peripheral devices
- power-saving architectural features
 - support for stop mode
 - support for doze mode

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- two sources of serialized data:
 - DSPI memory-mapped register
 - parallel input signals
 - programmable selection of source data on bit basis
- deserialized data provided as Parallel Output signals and as bits in a memory-mapped register
- interrupt conditions:
 - deserialized data matches pre-programmed pattern (DDIF)
 - Transfer of current DSI frame Complete (DSITCF)
 - DSI Parity Error (DPEF)
- DMA request support for following conditions: deserialized data matches pre-programmed pattern (DDIF)
- transfer initiation conditions:
 - continuous
 - edge sensitive hardware trigger
 - change in data
- support for parallel and serial chaining of several DSPI modules inside the MCU
- pin serialization/deserialization with interleaved SPI frames for control and diagnostics
- continuous serial communications clock

DSPI supports a combination of SPI and DSI modes of operation (Combined Serial Interface (CSI)) for the downstream Micro Second Channel in either Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration (configurable by software). Both TSB and Interleaved TSB modes have the following common features:

- transmission of frames is done at frame boundaries
- frames from SPI and DSI are identifiable by a bit transmitted at the start of each frame
- separate interrupts for frame completion from SPI and DSI

48.1.3 DSPI configurations

The DSPI module can operate in three configurations: SPI, DSI, and CSI.

48.1.3.1 SPI configuration

The SPI configuration allows the DSPI to send and receive serial data. This configuration allows the DSPI to operate as a basic SPI block with internal FIFOs supporting external queues operation. Transmit data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the receive FIFO and write transmit data to the transmit FIFO.

For queued operations, the SPI queues can reside in system RAM which is external to the DSPI. Data transfers between the queues and the DSPI FIFOs are accomplished by a DMA controller or host CPU. [Figure 732](#) shows a system example with DMA, DSPI and external queues in system RAM.

Figure 732. DSPI with queues and DMA

48.1.3.2 DSI configuration

In the DSI configuration the DSPI serializes up to 64 parallel input signals or register bits. The DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. The data is transferred using a SPI-like protocol.

TSB mode, detailed on [Section 48.4.9, Timed Serial Bus \(TSB\)](#), provides the Micro Second downstream Channel support (MSC), serializing from 4 to 64 parallel input signals or register bits. [Section 46.4.9, Timed Serial Bus \(TSB\)](#)

48.1.3.3 CSI configuration

There are three configurations available in this mode.

- The normal CSI configuration is a combination of the SPI and DSI configurations. In this configuration the DSPI interleaves DSI data frames with SPI data frames. Interleaving is done on the frame boundaries.
- In the TSB configuration, transmission of SPI data has higher priority than DSI data.
- In the Interleaved TSB (ITSB) configuration, the frames from SPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the SPI or the previous transmission was a frame from SPI. ITSB is detailed in [Section 48.4.10, Interleaved TSB \(ITSB\) Mode](#).

48.1.4 Modes of operation

The DSPI modes of operation that can be divided into two categories:

- Module-specific modes
 - Master mode
 - Slave mode
 - Module Disable mode
- MCU-specific modes
 - External Stop mode
 - Debug mode

The DSPI enters module-specific modes when the host writes a DSPI register. The MCU-specific modes are controlled by signals external to the DSPI. The MCU-specific modes are modes that an MCU may enter in parallel to the DSPI block-specific modes.

48.1.4.1 Master mode

Master mode allows the DSPI to initiate and control serial communication. In this mode, the SCK signal and the PCS[x] signals are controlled by the DSPI and configured as outputs.

48.1.4.2 Slave mode

Slave mode allows the DSPI to communicate with SPI/DSI bus masters. In this mode, the DSPI responds to externally controlled serial transfers. The SCK signal and the PCS[0]/SS signals are configured as inputs and driven by a SPI bus master.

48.1.4.3 Module Disable mode

The Module Disable mode can be used for MCU power management. The clock to the non-memory-mapped logic in the DSPI can be stopped while in Module Disable mode.

48.1.4.4 External Stop mode

External Stop mode is used for MCU power management. The DSPI supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, the DSPI block acknowledges the request and completes the transfer in progress. When the DSPI reaches the frame boundary it signals that the protocol clock to the DSPI module may be shut off.

48.1.4.5 Debug mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls DSPI behavior in the debug mode. If the bit is set, the DSPI stops all serial transfers, when the MCU is in Debug mode. If the bit is cleared, the MCU Debug mode has no effect on the DSPI.

48.2 DSPI signal description

This section provides the DSPI signals description.

[Table 777](#) lists the signals that may connect off chip depending on device implementation.

Table 777. DSPI signal description

Signal	Description	I/O
PCS0/ SS	Master mode: Peripheral Chip Select 0 output Slave mode: Slave Select input	I/O
PCS[3:1]	Master mode: Peripheral Chip Select 1–3 Slave mode: Unused	O
PCS4/ MTRIG	Master mode: Peripheral Chip Select 4 Slave mode: Master Trigger	O
PCS5/ PCSS	Master mode: Peripheral Chip Select 5 / Peripheral Chip Select Strobe Slave mode: Unused	O
PCS[7:6]	Master mode: Peripheral Chip Select 6–7 Slave mode: Unused	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O
SCK	Master mode: Serial Clock (output) Slave mode: Serial Clock (input)	I/O
HT	Hardware Trigger	I

48.2.1 $\overline{\text{PCS0/SS}}$ — Peripheral Chip Select/Slave Select

In master mode, the PCS0 signal is a Peripheral Chip Select output that selects which slave device the current transmission is intended for.

In slave mode, the active low $\overline{\text{SS}}$ signal is a Slave Select input signal that allows a SPI master to select the DSPI as the target for transmission.

48.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3

PCS1 – PCS3 are Peripheral Chip Select output signals in master mode.

In slave mode, these signals are unused.

48.2.3 $\overline{\text{PCS4/MTRIG}}$ — Peripheral Chip Select 4/Master Trigger

In master mode, PCS4 is a Peripheral Chip Select output signal.

In slave mode, the active low $\overline{\text{MTRIG}}$ is an output trigger signal that indicates that a change in data to be serialized has occurred. The MTRIG provides a pulse in DSI Configuration when a change in data to be serialized occurs. The MTRIG pulse is four protocol clock cycles in duration. If the DSPI is in slave mode and the MTO is disabled, the PCS4/ $\overline{\text{MTRIG}}$ signal is unused.

48.2.4 $\overline{\text{PCS5/PCSS}}$ — Peripheral Chip Select 5/Peripheral Chip Select Strobe

PCS5 is a Peripheral Chip Select output signal. When the DSPI is in master mode and the MCR[PCSSE] bit is cleared, this signal selects which slave device the current transfer is intended for.

When the DSPI is in master mode and the MCR[PCSSE] bit is set, the $\overline{\text{PCSS}}$ signal acts as a strobe to an external peripheral chip select demultiplexer, which decodes the PCS0 – PCS4 and PCS6 – PCS7 signals, preventing glitches on the demultiplexer outputs.

This signal is not used in slave mode.

48.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7

PCS[6] – PCS[7] are Peripheral Chip Select output signals in master mode. In slave mode, these signals are not used.

48.2.6 SIN — Serial Input

SIN is a serial data input signal.

48.2.7 SOUT — Serial Output

SOUT is a serial data output signal.

48.2.8 SCK — Serial Clock

SCK is a serial communication clock signal. In master mode, the DSPI generates the SCK. In slave mode, SCK is an input from an external bus master.

48.2.9 HT — Hardware Trigger

HT is a trigger input signal that is used with Multiple Transfer Operations in DSI Configuration.

In master mode while in DSI or CSI Configurations, the HT signal initiates a data transfer when the DSICR0[TRRE] bit is set and a rising or falling edge is detected on HT. Which edge to trigger on is determined by the DSICR0[TPOL] bit.

In slave mode, the DSPI generates a trigger pulse on the $\overline{\text{MTRIG}}$ pin, when a rising or falling edge is detected on HT. Which edge that generates an output pulse is selected by the DSICR0[TPOL] bit.

48.2.10 Memory map/register definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the DSPIx_POPR also results in a transfer error.

Table 778. DSPI memory map

Offset (hex)	Register name	Width (in bits)	Access	Reset value	Location

48.2.10.1 DSPI Module Configuration Register (DSPIx_MCR)

The DSPIx_MCR contains bits to configure various attributes associated with DSPI operations. The HALT and MDIS bits can be changed at any time, but they only take effect on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed while the DSPI is in the Running state.

Table 779. DSPIx_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Configures the DSPI for either master mode or slave mode. 0 DSPI is in slave mode. 1 DSPI is in master mode.
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously. 0 Continuous SCK disabled. 1 Continuous SCK enabled.
2–3 DCONF	DSPI Configuration Selects among the different configurations of the DSPI. 00 SPI 01 DSI 10 CSI 11 Reserved
4 FRZ	Freeze Enables the DSPI transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in debug mode. 1 Halt serial transfers in debug mode.

Table 779. DSPIx_MCR field descriptions (continued)

Field	Description
5 MTFE	Modified Timing Format Enable Enables a modified transfer format to be used. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS[5]/ PCSS to operate as a PCS Strobe output signal. 0 PCS[5]/ is used as the Peripheral Chip Select[5] signal. 1 PCS[5]/PCSS is used as an active-low PCS Strobe signal.
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the DSPI to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8–15 PC SIS[7:0]	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx when DSPI is in Master Mode. This field has no effect when DSPI is in Slave Mode. The Slave Select input to DSPI in slave mode is always Active Low. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.
16 DOZE	Doze Enable Provides support for an externally controlled Doze mode power-saving mechanism. 0 Doze mode has no effect on DSPI. 1 Doze mode disables DSPI.
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory-mapped logic in the DSPI effectively putting the DSPI in a software controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 1. When DSPI is used in Slave Mode, it is recommended to leave this bit set to '0', since a slave doesn't have control over master transactions. 0 Enable DSPI clocks. 1 Allow external logic to disable DSPI clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the DSPI (both TXFIFO and CMD FIFO) operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Tx FIFO is enabled. 1 Tx FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the DSPI operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 Rx FIFO is enabled. 1 Rx FIFO is disabled.

Table 779. DSPIx_MCR field descriptions (continued)

Field	Description
20 CLR_TXF	Clear TX FIFO Flushes the TX FIFO and the CMD FIFO. Writing a '1' to CLR_TXF clears the TX FIFO and CMD FIFO Counters. The CLR_TXF bit is always read as zero. 0 Do not clear the Tx FIFO and CMD FIFO counters. 1 Clears the Tx FIFO and CMD FIFO counters.
21 CLR_RXF	Flushes the RX FIFO. Writing a '1' to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. 0 Do not clear the Rx FIFO counter. 1 Clear the Rx FIFO counter.
22–23 SMPL_PT	Sample Point Controls when the DSPI master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTAR is 0. 00 0 protocol clocks between SCK edge and SIN sample 01 1 protocol clock between SCK edge and SIN sample 10 2 protocol clocks between SCK edge and SIN sample 11 Reserved
24–27 Reserved	This read-only bitfield is reserved and always has the value zero.
28 XSPI	Extended SPI Mode This bit enables usage of CTARE (Command and Transfer Attribute Register Extended) Registers. CTARE registers allow the user to send up to 32-bit SPI frames. Command Cycling is also enabled which allows the user to send multiple Data Frames using a single Command Frame. When MCR[DIS_TXF] is asserted, the Extended SPI Mode cannot be used to transmit SPI frames which are more than 16 bits in size. 0 Normal SPI Mode. Frame size can be up to 16 bits. Command Cycling is not available in this mode. 1 Extended SPI Mode. Up to 32-bit SPI Frames along with Command Cycling Enabled
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of "After SCK (t_{ASC})" and "PCS to SCK (t_{CSC})" delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHHR. The firmware should select appropriate masks when providing continuous frames via the PUSHHR. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHHR.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt Starts and stops DSPI transfers. 0 Start transfers. 1 Stop transfers.

48.2.10.2 DSPI Transfer Count Register (DSPIx_TCR)

The DSPIx_TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the DSPI is in the Running state.

Figure 734. DSPI Transfer Count Register (DSPIx_TCR)

Address: Base + 0x0008

Table 780. DSPIx_TCR field descriptions

Field	Description
0–15 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the DSPI makes. The SPI_TCNT field increments every time the last bit of a SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
16–31 Reserved	This read-only bitfield is reserved and always has the value zero.

48.2.10.3 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPIx_CTARn)

CTARs are used to define different transfer attributes. Do not write to the CTARs while the DSPI is in the Running state.

In master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 and CTAR1 are used to set the slave transfer attributes.

When the DSPI is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTARs is used. When the DSPI is configured as an SPI bus slave, the CTAR0 register is used.

When the DSPI is configured as a DSI master, the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0), selects which of the CTARs is used. When the DSPI is configured as a DSI bus slave, the CTAR1 register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is SPI data or DSI data. SPI transfers in CSI Configuration follow the protocol described for SPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration. CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields

Table 781. DSPIx_CTARn field descriptions

Field	Description
0 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in Table 782. See the BR field description for details on how to compute the baud rate. Refer to Table 782 for DSPI SCK duty cycle values. 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. The minimum valid FMSZ field value is 3. There is a constraint on the minimum allowable Frame size, which depends on the Register Read/Write clock to the Protocol Clock Ratio. The minimum Frame size (FMSZ + 1) is decided by the following equation. Upper Ceiling must be applied for non-integer values. $\text{Min. Frame Size} = (4 \times f_p) + (3 \times f_r) / (n \times f_r)$ fp = Protocol Clock Frequency fr = Register Read/Write Clock Frequency n = Multiple of protocol clock required to get Baud Clock - Given by $(\text{PBR} \times \text{BR}) / (1 + \text{DBR})$ However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Note that 'fp' can be equal to, less than or greater than 'fr' purely based on user requirement. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is used in 64 bit mode, then DSICR0[FMSZ4] also comes into picture while switching PCS assertion control.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the DSPI can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase or TSB mode Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. When the DSPI operates in TSB configuration, this bit should be set to be compliant to the MSC specification. 0 Data is transferred MSB first. 1 Data is transferred LSB first.

Table 781. DSPIx_CTARn field descriptions (continued)

Field	Description
8–9 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer to Section 48.4.5.2, PCS to SCK delay (tCSC) for more details. In the TSB mode, the PCSSCK field has no effect. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10–11 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. In the TSB mode, the PASC field has no effect. Refer to Section 48.4.5.3, After SCK delay (tASC) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12–13 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. In the TSB mode the PDT field defines two MSB bits of the Delay after Transfer. See the DT field description for details on how to compute the Delay after Transfer. Refer to Section 48.4.5.4, Delay after transfer (tDT) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
14–15 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3. 10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16–19 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. In the TSB mode the field has no effect. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_p) \times PCSSCK \times CSSCK$ Table 783 lists the delay scaler values. Refer to Section 48.4.5.2, PCS to SCK delay (tCSC) for more details.

Table 781. DSPIx_CTARn field descriptions (continued)

Field	Description
20–23 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer to Section 48.4.5.3, After SCK delay (tASC) for more details.
24–27 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period. The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer to Section 48.4.5.2, PCS to SCK delay (tCSC) for more details.
28–31 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: $SCK \text{ baud rate} = (f_P/PBR) \times [(1+DBR)/BR]$ Table 784 lists the baud rate scaler values.

Table 782. DSPI SCK duty cycle

48.2.10.4 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPIx_CTARn_SLAVE)

When the DSPI is configured as an SPI bus slave, the CTAR0 register is used.

When the DSPI is configured as a DSI master, the DSICTAS field in the DSPI DSI Configuration Register 0 (DSICR0), selects which of the CTARs is used. When the DSPI is configured as a DSI bus slave, the CTAR1 register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is SPI data or DSI data. SPI transfers in CSI Configuration follow the protocol described for SPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration. CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields.

Table 785. DSPIx_CTARn_SLAVE field descriptions

Field	Description
0–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the concatenated field {CTARn_SLAVE[FMSZ[5]], CTARn_SLAVE[FMSZ]} value plus 1. The minimum valid FMSZ field value is 3 (when FMSZ6 is 0).
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.

Table 785. DSPIx_CTARn_SLAVE field descriptions (continued)

Field	Description
6 CPHA	Clock Phase or TSB mode Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 FMSZ[5]	MSB of Frame Size when DSI is used in 64-bit Mode The number of bits transferred per frame is equal to the concatenated field {CTARn_SLAVE[FMSZ[5]], CTARn_SLAVE[FMSZ]} value plus 1.
10–31 Reserved	This read-only bitfield is reserved and always has the value zero.

48.2.10.5 DSPI Status Register (DSPIx_SR)

SR contains status and flag bits. The bits reflect the status of the DSPI and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear most of the flag bits in the SR by writing a '1' to them. Writing a 0 to a flag bit has no effect. This register may not be writable in module disable mode due to the use of power saving mechanisms.

Table 786. DSPIx_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a '1' to it. 0 Transfer not complete. 1 Transfer complete.
1 TXRXS	TX and RX Status Reflects the run status of the DSPI. 0 Transmit and receive operations are disabled (DSPI is in stopped state). 1 Transmit and receive operations are enabled (DSPI is in running state).
2 SPITCF	SPI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on SPI frame transmission completion in CSI Mode. This includes the ITSB Mode and 'TSB in CSI' Mode as well. This flag will not be asserted when DSPI is used in SPI or DSI Modes. 0 SPI frame transfer is not complete. 1 SPI frame transfer is complete.
3 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the DSPI is in master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a '1' to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.

Table 786. DSPIx_SR field descriptions (continued)

Field	Description
4 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for DSPI blocks operating in slave mode and SPI configuration. TFUF is set when the TX FIFO of a DSPI operating in SPI slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing '1' to it. 0 No Tx FIFO underflow. 1 Tx FIFO underflow has occurred.
5 DSITCF	DSI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on DSI frame transmission completion in CSI Mode. This includes the ITSB Mode and 'TSB in CSI' Mode as well. This flag will not be asserted when DSPI is used in SPI or DSI Modes. 0 DSI frame transfer is not complete. 1 DSI frame transfer is complete.
6 TFFF	Transmit FIFO Fill Flag Provides a method for the DSPI to request more entries to be added to the TX FIFO. The TFFF bit is set while the TX FIFO is not full. The TFFF bit can be cleared by writing '1' to it or by acknowledgement from the DMA controller to the TX FIFO full request. 0 Tx FIFO is full. 1 Tx FIFO is not full.
7 BSYF	Busy Flag This bit is valid only when DSPI_MCR[XSPI] is enabled. Indicates that the current Command Frame is being used for transmitting multiple data frames. This bit is not set for the last Data Frame of a Cyclic command Transfer or when DSPI_CTARE[DTCP] = 1. Refer to Section 48.4.2.5, Command First In First Out (CMD FIFO) buffering mechanism for more details. 0 No Cyclic Command Transfer in Progress. 1 Cyclic Command Transfer is in progress. Current Data Frame is not the last data frame for current cyclic command transfer.
8 CMDTCF	Command Transfer Complete Flag Indicates that the last Data frame for the current Cyclic Command has been transmitted. Hence this bit is set only for the last Data Frame of a Cyclic Command Transfer or when DSPI_CTARE[DTCP] = 1. CMDTCF remains set until it is cleared by writing a '1' to it. 0 Data Transfer by current Command not complete. 1 Data Transfer by current Command complete.
9 DPEF	DSI Parity Error Flag Indicates that a DSI frame with parity error had been received. The bit remains set until it is cleared by writing a '1' to it. 0 No parity error. 1 Parity error has occurred.
10 SPEF	SPI Parity Error Flag Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a '1' to it. 0 No parity error. 1 Parity error has occurred.

Table 786. DSPIx_SR field descriptions (continued)

Field	Description
11 DDIF	DSI Data Received with Active Bits Indicates that a DSI frame had been received with bits selected by DIMR with active polarity, defined by the DPIR. The bit remains set until it is cleared by writing a '1' to it. 0 No DSI data with active bits was received. 1 DSI data with active bits was received.
12 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The bit is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a '1' to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 TFIWF	Transmit FIFO Invalid Write Flag Indicates Data Write on TX FIFO while CMD FIFO is empty. Without a Command, the Data entries present in TXFIFO are invalid. 0 No Invalid Data present in TX FIFO 1 Invalid Data present in TX FIFO since CMD FIFO is empty
14 RFDF	Receive FIFO Drain Flag Provides a method for the DSPI to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 Rx FIFO is empty. 1 Rx FIFO is not empty.
15 CMDFFF	Command FIFO Fill Flag Provides a method for the DSPI to request more entries to be added to the CMD FIFO. The CMDFFF bit is set while the CMD FIFO is not full. The CMDFFF is cleared by writing a '1' to it or by acknowledgement from the DMA controller to the CMD FIFO full request. 0 CMD FIFO is full. 1 CMD FIFO is not full.
16–19 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the data part of PUSHR is written. The TXCTR is decremented every time the SPI data is transferred to the shift register.
20–23 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO Entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24–27 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28–31 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

48.2.10.6 DSPI DMA/Interrupt Request Select and Enable Register (DSPIx_RSER)

The DSPIx_RSER controls DMA and interrupt requests. Do not write to the RSER while the DSPI is in the Running state.

Table 787. DSPIx_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable Enables TCF flag in the SR to generate an interrupt request. 0 TCF interrupt requests are disabled. 1 TCF interrupt requests are enabled.
1 CMDFFF_RE	Command FIFO Fill Flag Request Enable Enables the CMDFFF flag in the SR to generate a request. The CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 CMDFFF interrupts or DMA requests are disabled. 1 CMDFFF interrupts or DMA requests are enabled.
2 SPITCF_RE	SPI Frame Transmission Complete Request Enable. The SPITCF_RE bit enables SPITCF flag in the SR to generate an interrupt request. 0 SPITCF interrupt requests are disabled. 1 SPITCF interrupt requests are enabled.
3 EOQF_RE	DSPI Finished Request Enable Enables the EOQF flag in the SR to generate an interrupt request. 0 EOQF interrupt requests are disabled. 1 EOQF interrupt requests are enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the SR to generate an interrupt request. 0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.

Table 787. DSPIx_RSER field descriptions (continued)

Field	Description
5 DSITCF_RE	DSI Frame Transmission Complete Request Enable. The DSITCF_RE bit enables DSITCF flag in the SR to generate an interrupt request. 0 DSITCF interrupt requests are disabled. 1 DSITCF interrupt requests are enabled.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the TFFF flag bit in the SR is set and the TFFF_RE bit in the RSER is set, this bit selects between generating an interrupt request or a DMA request. 0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
8 CMDTCF_RE	Command Transmission Complete Request Enable. The CMDTCF_RE bit enables CMDTCF flag in the SR to generate an interrupt request. 0 CMDTCF interrupt requests are disabled. 1 CMDTCF interrupt requests are enabled.
9 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the SR to generate an interrupt request. 0 DPEF interrupt requests are disabled. 1 DPEF interrupt requests are enabled.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
11 DDIF_RE	DSI data received with active bits Request Enable Enables the DDIF flag in the SR to generate an interrupt requests. 0 DDIF interrupt requests are disabled. 1 DDIF interrupt requests are enabled.
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the SR to generate an interrupt request. 0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
13 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables the TFIWF flag in the SR to generate an interrupt request. 0 TFIWF interrupt requests are disabled. 1 TFIWF interrupt requests are enabled.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled 1 RFDF interrupt or DMA requests are enabled

Table 787. DSPIx_RSER field descriptions (continued)

Field	Description
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
16 CMDFFF_DIRS	Command FIFO Fill DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. When the CMDFFF flag bit in the SR is set, and the CMDFFF_RE bit in the RSER is set, the CMDFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
17 DDIF_DIRS	DSI data received with active bits - DMA or Interrupt Request Select. Selects between generating a DMA request or an interrupt request. When the DDIF flag bit in the SR is set, and the DDIF_RE bit in the RSER is set, the DDIF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
18–31 Reserved	This read-only bitfield is reserved and always has the value zero.

48.2.10.7 DSPI PUSH FIFO Register In Master Mode (DSPIx_PUSHR)

PUSHR provides the means to write to the TX FIFO and CMD FIFO. Data written to this register is transferred to the TX FIFO and/or CMD FIFO. Eight- or sixteen-bit write accesses to the Data Field of PUSHR transfers the 16-bit Data field of PUSHR to the TX FIFO. Write accesses to the Command Field of PUSHR transfers the 16-bit Command Field of PUSHR to the CMD FIFO. The register structure is different in master and slave modes. In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO. In slave mode, CMD FIFO is unused and hence the 16-bit Command Field of PUSHR is reserved.

Unless Extended SPI Mode is being used, the TX FIFO and CMD FIFO must be filled simultaneously. In other words, write accesses must be given to both Data and Command fields of PUSHR for every PUSHR operation performed when MCR[XSPI] is 0. When Extended SPI Mode is disabled, since both TX FIFO and CMD FIFO are written to and read from simultaneously, they can be thought of as a single 32-bit FIFO.

When Extended SPI Mode is enabled, TX FIFO and CMD FIFO can be written independently. A PUSHR Read Operation returns the topmost TX FIFO and CMD FIFO entries concatenated.

When DSPI Module is disabled, any writes to this register will not update the FIFO. Hence any reads performed during Module disable mode will return the last PUSHR write performed when Module was enabled.

Table 788. DSPIx_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable Selects a Continuous Selection Format. The bit is used in SPI master mode. The bit enables the selected PCS signals to remain asserted between transfers. PUSHR[EOQ] and PUSHR[CONT] bits cannot be asserted together in any Command Frame, since EOQ signifies the last frame in a queue and the Last frame in a Continuous Transfer must have PUSHR[CONT] as 0. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1–3 CTAS	Clock and Transfer Attributes Select. Selects which CTAR (and corresponding CTARE register) to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI slave mode, CTAR0 is used. See the Chip Configuration chapter to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0/CTARE0 001 CTAR1/CTARE1 010 CTAR2/CTARE2 011 CTAR3/CTARE3 100 CTAR4/CTARE4 101 CTAR5/CTARE5 110 CTAR6/CTARE6 111 CTAR7/CTARE7
4 EOQ	End Of Queue Host software uses this bit to signal to the DSPI that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter. Clears the SPI_TCNT field in the TCR. The SPI_TCNT field is cleared before the DSPI starts transmitting the current SPI frame. Hence the current SPI frame will cause this counter to increment by 1. 0 Do not clear the TCR[SPI_TCNT] field. 1 Clear the TCR[SPI_TCNT] field.
6 PE_MASC	Parity Enable or Mask t_{ASC} delay in the current frame PE – This bit enables parity bit transmission and parity reception check for the SPI frame. MASC - The current frame has the “after SCK” delay masked if this bit is asserted. See Section 48.4.6.6, Fast Continuous Selection Format for more details. <i>Note: This bit is used as Mask t_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set.</i> 0 PE - No parity bit included/checked. MASC - TASC delay is not masked and the current frame has the after SCK delay. 1 PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - TASC delay is masked in the current frame.

Table 788. DSPIx_PUSHR field descriptions (continued)

Field	Description
7 PP_MCSC	Parity Polarity or Mask t_{CSC} delay in the next frame PP - It controls the polarity of the parity bit transmitted and checked. MCSC - The next frame has the "PCS to SCK" delay masked if this bit is asserted. See Section 48.4.6.6, Fast Continuous Selection Format for more details. <i>Note: This bit is used as Mask t_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set.</i> 0 PP - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC - TCSC delay is not masked and the next frame has the PCS to SCK delay. 1 PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC - TCSC delay is masked in the next frame.
8–15 PCS[7:0]	Select which PCS signals are to be asserted for the transfer. Refer to the chip configuration chapter for the number of PCS signals used in this MCU. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

48.2.10.8 DSPI PUSH FIFO Register In Slave Mode (DSPIx_PUSHR_SLAVE)

PUSHR provides the means to write to the TX FIFO. Data written to this register is transferred to the TX FIFO. Eight or 16-bit write accesses to the Data Field of PUSHR transfers the 16-bit Data Field of PUSHR to the TX FIFO. The register structure is different in master and slave modes. In master mode, the register provides 16-bit command to the CMD FIFO and 16-bit data to the TX FIFO. In slave mode, CMD FIFO is unused and hence the 16-bit Command Field of PUSHR is reserved.

In Slave mode, up to 32-bit SPI frames may be queued for transmission/reception by enabling MCR[XSPI] mode.

Table 789. DSPIx_PUSHR_SLAVE field descriptions

Field	Description
0–15 Reserved	This read-only bitfield is reserved and always has the value zero.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred.

48.2.10.9 DSPI POP FIFO Register (DSPIx_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Figure 741. DSPI POP FIFO Register (DSPIx_POPR)

Table 790. DSPIx_POPR field descriptions

Field	Description
0–31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

48.2.10.10 DSPI Transmit FIFO Registers (DSPIx_TXFRn)

TXFRn provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRn registers does not alter the state of the TX FIFO. Reading DSPIx_TXFRn registers is invalid for a DSPI Master when being used in the Extended SPI (XSPI) Mode.

Figure 742. DSPI Transmit FIFO Registers (DSPIx_TXFRn)

Address: Base + 0x003C

Access: User read-only

Table 791. DSPIx_TXFRn field descriptions

Field	Description
0–15 TXCMD_TXDATA	Transmit Command or Transmit Data In master mode, the TXCMD field contains the command that sets the transfer attributes for the SPI data. In slave mode, the TXDATA contains 16 MSB bits of the SPI data to be shifted out.
16–31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

48.2.10.11 DSPI Receive FIFO Registers (DSPIx_RXFRn)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFRs are read-only. Reading the RXFRn registers does not alter the state of the RX FIFO. The field MCR[MDIS] must be 0 when RXFR is read.

Figure 743. DSPI Receive FIFO Registers (DSPIx_RXFRn)

Table 792. DSPIx_RXFRn field descriptions

Field	Description
0–31 RXDATA	Receive Data Contains the received SPI data.

48.2.10.12 DSPI DSI Configuration Register 0 (DSPIx_DSICR0)

DSICR0 selects various attributes associated with DSI and CSI Configurations. Do not write to the DSICR0 while the DSPI is in the Running state.

Figure 744. DSPI DSI Configuration Register 0 (DSPIx_DSICR0)

Address: Base + 0x00BC

Table 793. DSPIx_DSICR0 field descriptions

Field	Description
0 MTOE	Multiple Transfer Operation Enable Enables multiple DSPIs to be connected in a parallel or serial configuration. The MTOE and TSB bits should not be set simultaneously. 0 Multiple transfer operation disabled. 1 Multiple transfer operation enabled.
1 FMSZ[4]	MSB of the frame size in master mode when DSI is used in 32-bit mode. If the bit is set, 16 is added to the frame size, as defined by the CTARn[FMSZ] field. The CTARx register is selected by the DSICTAS field.
2–7 MTOCNT[5:0]	Multiple Transfer Operation Count Selects the number of bits to be shifted out during a transfer in Multiple Transfer Operation. The field sets the number of SCK cycles that the bus master must generate to complete the transfer. The number of SCK cycles used is one more than the value in the MTOCNT field. The number of SCK cycles defined by MTOCNT must be equal to or greater than the frame size. When TSBC is set, MTOCNT has no effect.
8 FMSZ[5]	MSB of the frame size in master mode when DSI is used in 64-bit mode. If the bit is set, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ[4]], CTARn[FMSZ]} fields. The CTARx register is selected by the DSICTAS field. Hence the final concatenated frame size using this bit would be {DSICR0[FMSZ[5]], DSICR0[FMSZ[4]], CTARn[FMSZ]}. This field is only valid when DSICR1[DSI64] is enabled.
9 Reserved	This read-only bit is reserved. Note that this bit must always be written as zero.

Table 793. DSPIx_DSICR0 field descriptions (continued)

Field	Description
10 ITSB	Interleaved TSB mode. This bit enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are always sent when either the previous transmission was a SPI frame or if the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. The ITSB mode requires the DSICR0[TSBC] bit to be set and should be written only when MCR[HALT] bit is asserted. If ITSB bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit. See Section 48.4.10, Interleaved TSB (ITSB) Mode for more details. 0 Interleaved mode is disabled. 1 Interleaved mode is enabled.
11 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus Configuration, which allows up to 64-bit data to be used. It also allows t_{DT} to be programmable. 0 Timed Serial Bus Configuration disabled. 1 Timed Serial Bus Configuration enabled.
12 TXSS	Transmit Data Source Select. Selects the source of data to be serialized. The source can be either data from host software written to the DSPI DSI Alternate Serialization Data Register (ASDR1/0) or parallel input pin states latched into the DSPI DSI Serialization Data Register (SDR1/0). 0 Source of serialized data is the SDR. 1 Source of serialized data is the ASDR.
13 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal (HT), initiating DSI frames transfer. 0 Falling edge initiates a transfer. 1 Rising edge initiates a transfer.
14 TRRE	Trigger Reception Enable Enables the DSPI to initiate a DSI frames transfer with an external trigger signal. 0 Trigger signal reception disabled. 1 Trigger signal reception enabled.
15 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. When the CID bit is set, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out.
16 DCONT	DSI Continuous Peripheral Chip Select Enable Enables the PCS signals to remain asserted between transfers. The DCONT bit affects the PCS signals only in DSI master mode. When the TSBC bit is set, DCONT has no effect. 0 Return Peripheral Chip Select signals to their inactive state after the transfer is complete. 1 Keep Peripheral Chip Select signals asserted after transfer is complete.
17–19 DSICTAS[2:0]	DSI Clock and Transfer Attributes Select Selects the CTAR to use to provide transfer attributes for DSI frames. The DSICTAS field is used in DSI master mode. In DSI slave mode, CTAR1 is always selected.
20 DMS	Data Match Stop If set, stops DSI frame transmissions if DDIF flag is set in the SR. 0 DDIF flag does not have an effect on DSI frame transmissions. 1 DDIF flag stops DSI frame transmissions.

Table 793. DSPIx_DSICR0 field descriptions (continued)

Field	Description
21 PES	Parity Error Stop If set, stops DSI operation if the parity error happened in the received DSI frame. 0 Parity error does not stop DSI frame transmissions. 1 Parity error stops all DSI frame transmissions.
22 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
23 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of 1 bits is odd. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
24–31 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer. 0 Negate PCS[x]. 1 Assert PCS[x].

48.2.10.13 DSPI DSI Serialization Data Register 0 (DSPIx_SDR0)

SDR0 contains the states of the 32 LSB parallel input signals. The states of these parallel input signals are latched into the SDR0 on the rising edge of every protocol clock. The SDR0 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames. When DSICR1[DSI64E] is enabled, SDR1 forms the MSB half and SDR0 forms the LSB half of the 64-bit Serialization Data Register.

Figure 745. DSPI DSI Serialization Data Register 0 (DSPIx_SDR0)

Table 794. DSPIx_SDR0 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the signal states of the 32 LSB parallel input signals.

48.2.10.14 DSPI DSI Alternate Serialization Data Register 0 (DSPIx_ASDR0)

ASDR0 is used by host software to write the 32 LSB of the data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames. Writes to the ASDR0 take effect on the next frame boundary. When DSICR1[DSI64E] is enabled, ASDR1 forms the MSB half while ASDR0 forms the LSB half of the 64-bit Alternate Serialization Data Register.

Figure 746. DSPI DSI Alternate Serialization Data Register 0 (DSPIx_ASDR0)

Table 795. DSPIx_ASDR0 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the alternate 32 LSB of data to be serialized.

48.2.10.15 DSPI DSI Transmit Comparison Register 0 (DSPIx_COMPR0)

COMPR0 holds a copy of the 32 LSB of last transmitted DSI data. COMPR0 is read-only. DSI data is transferred to this register as it is loaded into the TX Shift Register. When DSICR1[DSI64E] is enabled, COMPR1 forms the MSB half while COMPR0 forms the LSB half of the 64-bit Transmit Comparison Register

Figure 747. DSPI DSI Transmit Comparison Register 0 (DSPIx_COMPR0)

Table 796. DSPIx_COMPR0 field descriptions

Field	Description
0–31 COMP_DATA	Compare Data Holds the 32 LSB of last serialized DSI data.

48.2.10.16 DSPI DSI Deserialization Data Register 0 (DSPIx_DDR0)

DDR0 holds the 32 LSB signal states for the Parallel Output signals. The DDR0 is read-only and host software can read data from incoming DSI frames. When DSICR1[DSI64E] is enabled, DDR1 forms the MSB half while DDR0 forms the LSB half of the 64-bit Deserialization Data Register.

Figure 748. DSPI DSI Deserialization Data Register 0 (DSPIx_DDR0)

Table 797. DSPIx_DDR0 field descriptions

Field	Description
0–31 DESER_DATA	Deserialized Data Holds 32 LSB of deserialized data that is presented as signal states to the Parallel Output signals.

48.2.10.17 DSPI DSI Configuration Register 1 (DSPIx_DSICR1)

DSICR1 selects various attributes associated with TSB (and ITSB) Configuration. The user must not write to the DSICR1 while the DSPI is in the Running state.

Figure 749. DSPI DSI Configuration Register 1 (DSPIx_DSICR1)

Table 798. DSPIx_DSICR1 field descriptions

Field	Description
0–1 Reserved	This read-only bitfield is reserved and always has the value zero.
2–7 TSBCNT[5:0]	Timed Serial Bus Operation Count When TSBC is set, TSBCNT defines the length of the data frame. The TSBCNT field valid value is from 3 to 63. The TSBCNT field selects the number of data bits to be shifted out during a transfer in TSB mode. The number of data bits in the data frame is one more than the value in the TSBCNT field.
8–12 Reserved	This read-only bitfield is reserved and always has the value zero.
13 DSI64E	DSI 64-bit Mode Enable When DSI64E is set, DSI Mode operates in 64-bit configuration allowing serialization and deserialization of Data frames up to 64 bits in size. The Extended Registers DSPIx_SDR1, DSPIx_AS DR1, DSPIx_COMPR1, DSPIx_DDR1, DSPIx_SSR1, DSPIx_PISR4-7, DSPIx_DIMR1, DSPIx_DPIR1 are only valid when this Mode is enabled. 0 DSI 64-bit Mode Disabled. DSI Mode operates in the default 32-bit configuration 1 DSI 64-bit Mode Enabled. DSI Mode operates in 64-bit configuration

Table 798. DSPIx_DSICR1 field descriptions (continued)

Field	Description
14 DSE1	Data Select Enable 1 When DSICR0[TBSC] bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTARn register, selected by the DSICR0[DSICTAS] field. If DSICR1[DSI64] is enabled, then the insertion bit position is defined by concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields. The TSBCNT field value must be greater than the FMSZ field value plus one for proper operation of the DSE1 bit. 0 No Zero bit is inserted in the middle of the data frame. 1 Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
15 DSE0	Data Select Enable 0 When DSICR0[TSBC] bit is set, the DSE0 bit controls insertion of the zero bit (Data Select) in the beginning of the Data frame. 0 No Zero bit is inserted in the beginning of the frame. 1 Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.
16–23 TRGPRD	Internal Trigger Period for the ITSB mode. When DSICR0[TRG] bit is cleared and ITSB Mode is enabled, this field determines the trigger period for the internal trigger in number of baud rate clock cycles. The trigger period should be calculated as: Trigger Period = 64 bits (DSI frame maximum size) + 2 selection bits (maximum) + t_{PF} (passive frame time) When DSICR1[DSI64E] is disabled, DSI frame maximum size is 32. Refer CTAR[FMSZ] field for minimum frame size allowed. See Interleaved TSB (ITSB) Mode for more details. 0 – 4 These values are invalid since minimum Command frame size is 5. (i.e. 1 selection bit + minimum frame size which is 4) 5 – 255 Number of baud rate clock cycles to be used as the trigger period. The trigger period implemented is equal to TRGPRD + 1.
24–31 DPCS1_x	DSI Peripheral Chip Select 0–7 These bits define the PCSs to assert for the second part of the DSI frame when operating in TSB (and ITSB) configuration with dual receiver. The DPCS1 bits select which of the PCS signals to assert during the second part of the DSI frame. The DPCS1 bits control the assertions of the PCS signals only in TSB and ITSB mode. 0 Negate PCS[x]. 1 Assert PCS[x].

48.2.10.18 DSPI DSI Serialization Source Select Register 0 (DSPIx_SSR0)

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and from SDR0. Each bit in the SSR0 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR0 register value has no effect. When DSICR1[DSI64E] is enabled, SSR1 forms the MSB half while SSR0 forms the LSB half of the 64-bit Serialization Source Select Register.

Figure 750. DSPI DSI Serialization Source Select Register 0 (DSPIx_SSR0)

Table 799. DSPIx_SSR0 field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 LSB of DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. 0The bit in the transmitted frame is taken from the parallel input pin. 1The bit in the transmitted frame is taken from the ASDR0 register

48.2.10.19 DSPI DSI Parallel Input Select Register 0 (DSPIx_PISR0)

PISR0–3 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 if DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–3 only preselect the parallel input pins. The final selection to the transmitted frame is made with the DSPI_SSR1/0 register bits or the DSICR0[TXSS] bit.

When DSICR1[DSI64E] is enabled, PISR4-7 Registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins).

48.2.10.23 DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPIx_DIMR0)

DIMR0 selects bits in the 32 LSB of received DSI frame to be checked to generate the DDI interrupt. When DSICR1[DSI64E] is enabled, DIMR1 forms the MSB half while DIMR0 forms the LSB half of the 64-bit Deserialized Data Interrupt Mask Register.

Figure 755. DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPIx_DIMR0)

Table 804. DSPIx_DIMR0 field descriptions

Field	Description
0–31 MASK	Mask Defines which bits in the 32 LSB of received deserialization data should be checked to produce the Deserialized Data Interrupt (DDI). 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame can produce a DDI interrupt if the data bit matches the configured polarity.

48.2.10.24 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPIx_DPIR0)

DPIR0 defines which data bit value in the 32 LSB of received DSI frame generates the DDI interrupt. When DSICR1[DSI64E] is enabled, DPIR1 forms the MSB half while DPIR0 forms the LSB half of the 64-bit Deserialized Data Polarity Interrupt Register.

Figure 756. DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPIx_DPIR0)

Table 805. DSPIx_DPIR0 field descriptions

Field	Description
0–31 DP	Data Polarity Defines which value of the 32 LSB of received deserialization data sets the SR[DDIF] bit. 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

48.2.10.25 DSPI DSI Serialization Data Register 1 (DSPIx_SDR1)

SDR1 contains the states of the 32 MSB parallel input signals. The states of these parallel input signals are latched into the SDR1 on the rising edge of every protocol clock. The SDR1 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR1 and SDR0 is used as the source of the DSI frames. The concatenation of {DSPIx_SDR1, DSPIx_SDR0} provides the 64-bit data to be serialized. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 757. DSPI DSI Serialization Data Register 1 (DSPIx_SDR1)

Table 806. DSPIx_SDR1 field descriptions

Field	Description
0–31 SER_DATA	Serialized Data Contains the 32 MSB signal states of the 64 parallel input signals. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_SDR1, DSPIx_SDR0} provides the 64-bit data to be serialized.

48.2.10.26 DSPI DSI Alternate Serialization Data Register 1 (DSPIx_ASDR1)

ASDR1 is used by host software to write the 32 MSB of the 64-bit data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR1 and ASDR0 is the source of the DSI frames. Writes to the ASDR1 take effect on the next frame boundary. The concatenation of {DSPIx_ASDR1, DSPIx_ASDR0} provides the 64-bit alternate serialization data. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 758. DSPI DSI Alternate Serialization Data Register 1 (DSPIx_ASDR1)

Table 807. DSPIx_ASDR1 field descriptions

Field	Description
0–31 ASER_DATA	Alternate Serialized Data Holds the 32 MSB of the 64-bit alternate data to be serialized. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_ASDR1, DSPIx_ASDR0} provides the 64-bit alternate serialization data.

48.2.10.27 DSPI DSI Transmit Comparison Register 1 (DSPIx_COMPR1)

COMPR1 holds a copy of the 32 MSB of the last transmitted 64-bit DSI data. COMPR1 is read-only. The upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift Register. The concatenation of {DSPIx_COMPR1, DSPIx_COMPR0} provides the 64-bit transmit comparison data. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 759. DSPI DSI Transmit Comparison Register 1 (DSPIx_COMPR1)

Table 808. DSPIx_COMPR1 field descriptions

Field	Description
0–31 COMP_DATA	Compare Data Holds the 32 MSB of the last serialized 64-bit DSI data. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_COMPR1, DSPIx_COMPR0} provides the last serialized 64-bit DSI data.

48.2.10.28 DSPI DSI Deserialization Data Register 1 (DSPIx_DDR1)

DDR1 holds the 32 MSB signal states for the 64 Parallel Output signals. The DDR1 is read-only and host software can read data from incoming DSI frames.

The concatenation of {DSPIx_DDR1, DSPIx_DDR0} provides the 64-bit Deserialized data. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 760. DSPI DSI Deserialization Data Register 1 (DSPIx_DDR1)

Table 809. DSPIx_DDR1 field descriptions

Field	Description
0–31 DESER_DATA	Deserialized Data Holds 32 MSB of the deserialized data that is presented as signal states to the 64 Parallel Output signals. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_DDR1, DSPIx_DDR0} provides the 64-bit deserialized data.

48.2.10.29 DSPI DSI Serialization Source Select Register 1 (DSPIx_SSR1)

SSR1 is used to create a combined frame for transmission that contains bits from ASDR1 and from SDR1. Each bit in the SSR1 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR1 register value has no effect. The concatenation of {DSPIx_SSR1, DSPIx_SSR0} provides the 64-bit Serialization Source Select Value. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 761. DSPI DSI Serialization Source Select Register (DSPIx_SSR)

Table 810. DSPIx_SSR field descriptions

Field	Description
0–31 SS	Source Select Select the serialization source for the 32 MSB of the 64-bit DSI frame. Each SS bit selects data for a corresponded bit in the transmitted frame. This field is valid only when DSICR1[DSI64E] is set. The concatenation of {DSPIx_SSR1, DSPIx_SSR0} provides the 64-bit serialization source select value. 0The bit in the transmitted frame is taken from the parallel input pin. 1The bit in the transmitted frame is taken from the ASDR1 register

48.2.10.30 DSPI DSI Parallel Input Select Register 4 (DSPIx_PISR4)

PISR4–7 are used to select each data bit for the transmitted frame from 16 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31 (bit 0 is taken from parallel input 63 when DSICR1[DSI64E] is enabled). When the IPS0 is equal to +1, then bit 0 in the frame is taken from parallel input 1 and so on.

Note that PISR0–7 only preselect the parallel input pins. The final selection to the transmitted frame is made with the SSR0 and SSR1 register bits or the DSICR0[TXSS] bit.

When 64-bit DSI mode is enabled, PISR4-7 Registers are used to handle the extra 32 bits (32 MSB pins of the 64 parallel input pins). If DSICR1[DSI64E] is disabled, then DSPIx_PISR4-7 Registers are invalid.

48.2.10.34 DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPIx_DIMR1)

DIMR1 selects bits from the 32 MSB in the received 64-bit DSI frame to be checked to generate the DDI interrupt. The concatenation of {DSPIx_DIMR1, DSPIx_DIMR0} provides the 64-bit Deserialized Data Interrupt Mask Value. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 766. DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPIx_DIMR1)

Table 815. DSPIx_DIMR1 field descriptions

Field	Description
0–31 MASK	Mask Defines which of the 32 MSB in the received 64-bit deserialization data should be checked to produce the Deserialized Data Interrupt (DDI). 0 The bit in the received DSI frame does not produce a DDI interrupt. 1 The bit in the received DSI frame can produce a DDI interrupt if the data bit matches the configured polarity.

48.2.10.35 DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPIx_DPIR1)

DPIR1 defines which of the 32 MSB value in the received 64-bit DSI frame generates the DDI interrupt. The concatenation of {DSPIx_DPIR1, DSPIx_DPIR0} provides the 64-bit Deserialized Data Polarity Value. This register is valid only when DSICR1[DSI64E] is enabled.

Figure 767. DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPIx_DPIR1)

Table 816. DSPIx_DPIR1 field descriptions

Field	Description
0–31 DP	Data Polarity Defines which of the 32 MSB of the received 64-bit deserialization data sets the SR[DDIF] bit. 0 If the received bit is 0, the SR[DDIF] bit is set. 1 If the received bit is 1, the SR[DDIF] bit is set.

48.2.10.36 DSPI Clock and Transfer Attributes Register Extended (DSPIx_CTAREn)

CTARE registers are used to define the extended transfer attributes for an SPI frame. These registers are valid only when DSPIx_MCR[XSPI] is set.

When the DSPI is configured as an SPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used. When the DSPI is configured as an SPI bus slave, the CTARE0 register is used.

Table 817. DSPIx_CTAREn field descriptions

Field	Description
16 FMSZE	Frame Size Extended This field is valid only when DSPIx_MCR[XSPI] is set. This field concatenated with DSPIx_CTAR[FMSZ] defines the frame size of the SPI frames to be transmitted. Effective frame size is the concatenation of {DSPIx_CTAR[FMSZ], DSPIx_CTARE[FMSZE]} plus 1. 0Default Mode. Up to 16-bit SPI frames can be transferred. 1Up to 32-bit SPI frames can be transferred. Each frame transfer will be a result of 2 TX FIFO Pops.
21–31 DTCP	Data Transfer Count Preload This field is valid only when DSPIx_MCR[XSPI] is set. This field defines the number of data frames (whose size is defined by CTARE[FMSZE] and CTAR[FMSZ]) to be transmitted using the Command frame that selected this DSPIx_CTARE register. The value 0 is reserved and should not be written in this field. The default value of this field is 1.

48.2.10.37 DSPI Status Register Extended (DSPIx_SREX)

The DSPIx_SREX contains status fields. The fields reflect the status of the DSPI and indicate the occurrence of events. This register is not writable.

Figure 769. DSPI Status Register Extended (DSPIx_SREX)

Address: Base + 0x013C

Table 818. DSPIx_SREX field descriptions

Field	Description
24–27 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. The CMDCTR is incremented every time the command part of PUSHR is written. The CMDCTR is decremented every time a SPI command is executed (all data frames due to current command frame have been transmitted).
28–31 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO Entry is used during the next transfer. The CMDNXTPTR field is updated every time SPI data due to current command have been transmitted.

48.3 Register classification for safety

The registers of this module are classified as per safety requirements as follows:

Safety Critical: There are no safety critical registers in this module.

Safety Relevant: The register bits/fields in this category are safety relevant as any random error in these bits will lead to unwanted interference to CPU. The registers containing these fields must be protected by periodic CRC or equivalent check implemented at chip level. The following register bits/fields are classified in this category:

- DSPI Module Configuration Register (DSPIx_MCR)
- DSPI Transfer Count Register (DSPIx_TCR)
- DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPIx_CTARn)
- DSPI Clock and Transfer Attributes Extended Register (In Master Mode) (DSPIx_CTAREN)
- DSPI DMA/Interrupt Request Select and Enable Register (DSPIx_RSER)

- DSPI PUSH FIFO Register In Master Mode (DSPIx_PUSHR) [0:15]
- DSPI DSI Configuration Register 0 (DSPIx_DSICR0)
- DSPI DSI Configuration Register 1 (DSPIx_DSICR1)

Safety Latent: The register bits/fields in this category should be protected by LBIST at chip level. The following register bits/fields are classified in this category:

- DSPI Status Register (DSPIx_SR) [0:15] (for stuck at 0)
- DSPI Status Register Extended (DSPIx_SREX) [0:8] (for stuck at 0)
- DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPIx_DIMR0)
- DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPIx_DIMR1)
- DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPIx_DPIR0)
- DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPIx_DPIR1)

Non-Safety: All other registers and bits fall in this category.

48.4 Functional description

The Deserial Serial Peripheral Interface (DSPI) block supports full-duplex, synchronous serial communications between MCUs and peripheral devices. The DSPI can also be used to reduce the number of pins required for I/O by serializing and deserializing up to 64 parallel input/output signals. All communications are done with SPI-like protocol.

The DSPI has the following configurations:

- SPI Configuration in which the DSPI operates as a basic SPI or a queued SPI.
- DSI Configuration in which the DSPI serializes and deserializes Parallel Input/Output signals or bits from memory-mapped register.
- CSI Configuration in which the DSPI combines the functionality of the SPI and DSI configurations.

The DCONF field in the DSPI Module Configuration Register (MCR) determines the DSPI Configuration. See [Section 48.2.10.1, DSPI Module Configuration Register \(DSPIx_MCR\)](#) for the DSPI configuration values.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command. The Extended SPI Mode (DSPIx_MCR[XSPI]) further allows the usage of CTAREn (CTARn Extended) registers which allows the user to send multiple Data frames (of up to 32-bit frame size) using a single Command frame.

The DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if SPI data or DSI data is transferred and dictates what CTAR is used for the data transfer.

See DSPI Clock and Transfer Attributes Registers for information on the fields of the CTARs.

See DSPI Clock and Transfer Attributes Registers Extended for information on the fields of the CTARE registers.

Typical master to slave connections are shown in [Figure 770](#). When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The

data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the TCF bit in the SR is set to indicate a completed transfer.

Figure 770. SPI serial protocol overview

Generally more than one slave device can be connected to the DSPI master.

Eight Peripheral Chip Select (PCS) signals of the DSPI masters can be used to select which of the slaves to communicate with. Refer to the chip configuration chapter for the number of PCS signals used in this MCU.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in [Section 48.4.6, Transfer formats](#). The transfer rate and delay settings are described in [Section 48.4.5, DSPI baud rate and clock delay generation](#).

48.4.1 Start and Stop of DSPI transfers

The DSPI has two operating states: STOPPED and RUNNING. The states are independent of DSPI configuration. The default state of the DSPI is STOPPED. In the STOPPED state no serial transfers are initiated in master mode and no transfers are responded to in slave mode. The STOPPED state is also a safe state for writing the various configuration registers of the DSPI without causing undetermined results. In the RUNNING state serial transfers take place.

The TXRXS bit in the SR indicates what state the DSPI in. The bit is set if the module in RUNNING state.

The DSPI is started (DSPI transitions to RUNNING) when all of the following conditions are true:

- SR[EOQF] bit is clear
- MCU is not in the debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The DSPI stops (transitions from RUNNING to STOPPED) after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- MCU in the debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from RUNNING to STOPPED occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

48.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The DSPI is in SPI Configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to DSPI RAM queues to a transmit FIFO (TX FIFO) buffer. The received data is stored in entries in the Receive FIFO (RX FIFO) buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the DSPI. The FIFO buffers operation is described in [Section 48.4.2.4, Transmit First In First Out \(TX FIFO\) buffering mechanism](#), [Section 48.4.2.5, Command First In First Out \(CMD FIFO\) buffering mechanism](#) and [Section 48.4.2.6, Receive First In First Out \(RX FIFO\) Buffering Mechanism](#). The interrupt and DMA request conditions are described in [Section 48.4.12, Interrupts/DMA requests](#).

The SPI Configuration supports two block-specific modes —master mode and slave mode. In master mode, the DSPI initiates and controls the transfer according to the fields of the executing CMD FIFO entry. In slave mode, the DSPI only responds to transfers initiated by a bus master external to the DSPI and the SPI command field space is reserved.

48.4.2.1 Master Mode

In SPI master mode the DSPI initiates the serial transfers by controlling the Serial Communications Clock (SCK) and the Peripheral Chip Select (PCS) signals. The executing SPI CMD FIFO entry determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See DSPI PUSH FIFO Register (PUSHR) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI master mode, each SPI frame to be transmitted has a command associated with it allowing for transfer attribute control on a frame by frame basis. In Extended SPI Master Mode, multiple SPI frames can have a single command associated with them allowing for efficient SPI frame transfers requiring common transfer attributes. In addition, the Extended SPI Mode allows for larger frame sizes of up to 32 bits.

48.4.2.2 Slave Mode

In SPI slave mode the DSPI responds to transfers initiated by a SPI bus master. The DSPI does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase and frame size must be set for successful communication with a SPI master. The SPI slave mode transfer attributes are set in the CTAR0 and CTARE0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

48.4.2.3 FIFO Disable Operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The DSPI operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately; setting the MCR[DIS_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO Disable mechanisms are transparent to the user and to host software; Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO is disabled (CMD FIFO is also disabled), the TFFF, TFUF, CMDFFF, CMDCTR and TXCTR fields in SR, SREX behave as if there is a one-entry FIFO but the contents of the TXFR registers, TXNXTPTR and CMDNXTPTR are undefined. Likewise, when the RX FIFO is disabled, the RFDF, RFOF and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

48.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data field of DSPI PUSH FIFO Register (PUSHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place to the Data field of DSPI_PUSH or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates which TX FIFO Entry will be transmitted during the next transfer. The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO are used separately. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

48.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSH. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSH is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Section 48.4.12.2, Transmit FIFO Fill interrupt or DMA request](#) for details.

The DSPI ignores attempts to push data to a full TX FIFO, the state of the TX FIFO does not change and no error condition is indicated.

48.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, if the frame size of SPI Data to be transmitted is more than 16 bits, then it causes two Data entries to be popped from TX FIFO simultaneously which are transferred to the shift register. The first of the two popped entries forms the 16 LSB bits of the SPI frame. Such an operation also causes TX FIFO Counter to decrement by two. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a DSPI slave while the slave's DSPI TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Section 48.4.12.9, Transmit FIFO Underflow interrupt request](#) for details.

48.4.2.5 Command First In First Out (CMD FIFO) buffering mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. When Extended SPI Mode (DSPIx_MCR[XSPI]) is disabled, the TX FIFO and CMD FIFO must be filled together. When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, the TX FIFO and CMD FIFO can be filled independently.

The CMD FIFO holds four entries, each representing command fields. The number of entries in the CMD FIFO is device-specific. SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is disabled, every CMD FIFO entry has a corresponding single TXFIFO entry attached to it.

When Extended SPI Mode (DSPIx_MCR[XSPI]) is enabled, every CMD FIFO entry can have multiple TXFIFO entries attached to it. Thus a single CMD FIFO entry can be used to transmit multiple TX FIFO entries. The CTARE[DTCP] field decides the number of SPI Data Frames having frame size as {FMSIZE, FMSZ} to be transmitted using the current Command Entry. The CTAR/CTARE registers pointed by the CTAS field in the Command frame gives FMSZ and FMSIZE fields respectively. The time for which a command entry is in use is known as a Command Cycle. The Busy Flag SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the CMD FIFO. The TXCTR is updated every time an 8 or 16-bit write takes place on the lower half of DSPI_PUSH or SPI data is transferred into the shift register from the TX FIFO.

The CMDNXTPTR field indicates which CMD FIFO Entry will be used during the next command cycle. The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO are used separately. The CMDNXTPTR field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR register number and it rolls over after reaching the maximum.

48.4.2.6 Receive First In First Out (RX FIFO) Buffering Mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds four received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the DSPI POP FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the DSPI Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR register number and it rolls over after reaching the maximum.

48.4.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time a SPI frame is transferred to the RX FIFO the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

48.4.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the DSPI POP FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a '1' to it.

48.4.3 Deserial Serial Interface (DSI) configuration

The DSI Configuration supports pin count reduction by serializing parallel input signals or register bits and shifting them out in a SPI-like protocol. The timing and transfer protocol is described in [Section 48.4.6, Transfer formats](#). The received serial frames are converted to a parallel form (deserialized) and placed on the Parallel Output signals or in the DSPI_DDR. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI_DSICR1/0).

The DSI frames can be from 4 to 32 bits. This can go up to 64 bits when DSICR1[DSI64E] is enabled. With Multiple Transfer Operation (MTO) the DSPI supports serial chaining of DSPI blocks within a device to create DSI frames up to 64 bits, consisting of concatenated bits from multiple DSPIs. The DSPI also supports parallel chaining allowing several DSPIs and off-chip SPI devices to share the same Serial Communications Clock (SCK) and Peripheral Chip Select (PCS) signals. See [Section 48.4.3.6, Multiple Transfer Operation \(MTO\)](#) for details on the serial and parallel chaining support.

Multiple Transfer Operation (MTO) and DSICR1[DSI64E] are not supported together and cannot be enabled simultaneously.

48.4.3.1 DSI master mode

In DSI master mode the DSPI initiates and controls the DSI transfers. The DSI master has four different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal
- Trigger signal combined with a change in data

The four transfer initiation conditions are described in [Section 48.4.3.5, DSI transfer initiation control](#). Transfer attributes are set during initialization. DSICR0[DSICTAS] field determines which of the DSPI_CTARs will control the transfer attributes.

48.4.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a SPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers. Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI_CTAR1. The data is shifted out with MSB first.

If DSICR0[CID] is set and the data in the DSPI_COMPR1/0 differs from the selected source of the serialized data, the slave DSPI will assert the MTRIG signal. If the slave's HT signal is asserted and the TRRE is set, the slave DSPI asserts MTRIG. These features are included to support chaining of several DSPI. Details about the MTRIG signal can be found in [Section 48.4.3.6, Multiple Transfer Operation \(MTO\)](#).

48.4.3.3 DSI serialization

In the DSI configuration from 4 to 16 bits can be serialized using two different sources. DSICR0[TXSS] bit selects between the DSPI DSI Serialization Data Register (DSPI_SDR1/0) and the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0) as the source of the serialized data. The DSPI_SDR0 holds the latest 32 parallel input signal values which is sampled at every rising edge of the protocol clock. When DSICR1[DSI64E] is enabled, 64-bit DSI Frames are supported and hence DSPI_SDR1 holds the 32 MSB parallel input signal values which is sampled at every rising edge of the protocol clock. The DSPI_ASDR1/0 registers are written by host software and used as an alternate source of serialized data. (DSPI_ASDR1 is only usable when DSICR1[DSI64E] is enabled).

The DSPI has to sample the (SDR/ASDR) inputs before it transmits a DSI frame. Due to the asynchronous Clock structure within DSPI, the sampling of inputs come under Register Clock domain whereas DSI frame transmission logic lies in Protocol Clock domain. Hence the sampled data (from ASDR1/0 or SDR1/0) must be synchronized into the Protocol Domain before being loaded into the Shift Register for transmission.

To prevent Clock Domain clocking issues, SDR/ASDR inputs should not change while they are being sampled into the Protocol Domain. This is ensured in the following manner for the ASDR inputs. The initial write performed on ASDR register will cause the 32-bit ASDR input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain. Once synchronized, the lock is removed and the next ASDR write will again trigger this process. If there was a write performed on ASDR while the lock was asserted, this will be taken into consideration as soon as the previous synchronization process completes and lock gets de-asserted.

In case, multiple writes were performed on ASDR when lock was asserted after the first write, only the latest value will be considered for synchronization once the lock gets de-asserted. The above locking scheme and the synchronization procedure is true for both ASDR0 and ASDR1 registers. The entire process explained above is also true for the SDR0 and SDR1 inputs, the only difference being that SDR inputs are delayed internally by a single clock to detect a change in the SDR input pins.

Note: *If SDR0 and SDR1 inputs are both changed at the same time instant, then the synchronization logic ensures that both SDR0 and SDR1 contribute to the same DSI frame.*

Once the synchronization process for a particular Deserial input begins, it takes up to five Register clock periods and five Protocol clock periods before the synchronization process for the next Deserial input can begin. Hence the writes performed on ASDR0/1 and SDR0/1 are constrained with this timing.

The DSPI_PISR0–3 registers (DSPI_PISR0–7 registers if DSICR1[DSI64E] is enabled) allow to change the relative position of the Parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent parallel inputs by writing IPS_n fields. The IPS_n field is treated as a 4-bit integer number, representing numbers from -8 to 7. The parallel input pin number, selected by IPS_n field is defined by the sum of the IPS_n field number (*n*) and the IPS_n field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result. (When DSICR1[DSI64E] is enabled, if the above operation result is negative, the number 64 should be added. If the result is higher than 64, 64 should be subtracted from the result).

For example, IPS0, set to minus 1 (binary 1111), preselects parallel input 31 to 0 position in the transmitted frame. (This preselects parallel input 63 to 0 position in the transmitted frame when DSICR1[DSI64E] is set).

IPS6, set to 3 (binary 0011), preselects parallel input 9 to be bit number 6 in the transmitted frame, while the value minus 2 (1110) preselects parallel input 4.

IPS31, set to minus 8 (binary 1000), preselects parallel input 23 to be bit number 31 in the transmitted frame.

The parallel input pin state, to be transmitted, should be selected by TXSS or DSPI_SSR1/0 registers and the frame size should be higher than the bit position in the preselected frame.

DSPI_SSR1/0 registers provide additional way to create the frame for transmission. Each bit from this register is OR'd with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI_SDR1/0 and DSPI_AS DR1/0 bits. This feature allows control SPI based devices, requiring control and data fields in the frame. The control field may come from DSPI_AS DR1/0 registers, set by the CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift Register is stored in the DSPI DSI Transmit Comparison Registers (DSPI_COMP R1/0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. [Figure 771](#) shows the DSI serialization logic.

Figure 771. DSI serialization diagram

48.4.3.4 DSI deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI_DDR1/0). This register presents the deserialized data as Parallel Output signal values. The DSPI_DDR1/0 is memory-mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI_DPIR1/0), bit-wise AND'ed with DSI Deserialized Interrupt Mask Register (DSPI_DIMR1/0) and the results OR'ed to produce DDIF flag in the DSPI_SR. Which in turn can cause DDIF interrupt request or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] bits and/or stop DSI frame transmissions if DSICR0[DMS] bit is set. [Figure 772](#) shows the DSI Deserialization logic.

Figure 772. DSI deserialization diagram

48.4.3.5 DSI transfer initiation control

Data transfers for a master DSPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI_DSICR0 register. [Table 819](#) lists the four transfer initiation conditions.

Table 819. DSI data transfer initiation control

DSPI_DSICR0 bits		Transfer initiation control
TRRE	CID	
0	0	Continuous
0	1	Change in Data
1	0	Triggered
1	1	Triggered or Change in Data

48.4.3.5.1 Continuous control

For continuous control, a new DSI frame shifts out when the previous transfer cycle has completed and the delay after transfer (t_{DT}) has elapsed.

48.4.3.5.2 Change in data control

For change in data control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in the DSPI_COMPR1/0. When the data, selected for the transfer from the DSPI_SDR1/0 and DSPI_AS DR1/0 registers is different from the data in the DSPI_COMPR1/0 a new DSI frame is transmitted. The MTRIG output signal is asserted every time a change in data is detected.

48.4.3.5.3 Triggered control

For Triggered Control, initiation of a transfer is controlled by the Hardware Trigger signal (HT). DSICR0[TPOL] bit selects the active edge of HT. For HT to have any affect, DSICR0[TRRE] bit must be set.

48.4.3.5.4 Triggered or change in data control

For triggered or change in data control initiation of a transfer is controlled by the HT signal or by the detection of a change in data to be serialized.

It is not advisable to configure a DSPI Slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1; since the following statement then holds true.

Once slave select is asserted, there is a very small window (of up to three module clocks), after every SOF (Start of Frame) during which if a write on AS DR/SDR registers occur, the next frame to be transmitted would be loaded into the shift register. However it is not feasible that such a write is initiated and completed within this short span of time; hence the data transmitted by DSPI slave would lag by one data frame.

48.4.3.6 Multiple Transfer Operation (MTO)

In DSI configuration, the MTO feature allows for multiple DSPIs within a device to be chained together in a parallel or serial configuration. The parallel chaining allows multiple DSPIs internal to a device and multiple SPI devices external to a device to share SCK and

PCS signals, thereby saving the device pins. The serial chaining allows bits from multiple DSPIs to be concatenated into a single DSI frame. MTO is enabled by setting DSICR0[MTOE] bit.

In parallel and serial chaining there is one bus master and multiple bus slaves. The bus master initiates and controls the transfers, but the DSPI slaves generate trigger signals for the bus DSPI master when an internal condition in the slave warrants a transfer. The DSPI slaves also propagate triggers from other slaves to the master. When a DSPI slave detects a trigger signal on its HT input, the slave generates a trigger signal on the MTRIG output. Serial and parallel chaining require multiplexing of signals external to the DSPI.

TSB operation is not available in MTO mode. DSICR0[TSBC] and DSICR0[MTOE] bits should not be set simultaneously.

DSI64 mode is also not available in MTO Mode. DSICR1[DSI64E] and DSICR0[MTOE] bits must not be set simultaneously.

48.4.3.6.1 Parallel chaining

Parallel chaining allows multiple DSPIs internal to a device and multiple SPI/DSI devices external to a device to share common SCK and PCS signals thereby saving pins. Two pins are saved per pair of DSPI/SPI. [Figure 773](#) shows an example of how the blocks can be connected in a device.

Figure 773. Example of parallel chaining of DSPIs

The DSPI master controls and initiates all transfer, but the DSPI slaves have a trigger output signal MTRIG that indicates to the master DSPI to start a transfer. When the DSPI slave has a change in its data to be serialized, it generates a pulse on the MTRIG signal to the master DSPI, which initiates the transfer. When a DSPI slave has its HT signal asserted it also generates a pulse on its MTRIG signal thereby propagating trigger signals from other DSPI slaves to the DSPI master.

To enable MTRIG signals generation the MTO has to be enabled for the DSPI slaves. The chained DSPI modules also should be in DSI configuration. The DSPI_DSICR0[MTOCNT] field must be written with the same number of bits to be transferred for each slave DSPI.

The MTOCNT value must also match the FMSZ field of the DSPI_CTAR1 in the DSPI slaves and selected DSPI_CTAR for the master DSPI module.

48.4.3.6.2 Serial chaining

The serial chaining allows transfers of DSI frames of up to a total of 64 bits, using transfers of smaller DSI frames concatenated together by multiple DSPIs. [Figure 774](#) shows an example of how the blocks can be connected in a device.

Figure 774. Example of serial chaining of DSPIs

The SOUT of the DSPI master is connected to the SIN of the first DSPI slave. The SOUT of the first DSPI slave is connected to the SIN input of the second slave and so on. The SOUT of the last DSPI slave is connected to the SIN of the external SPI slave. The SOUT of the external SPI slave is connected to the SIN of the DSPI master.

The DSPI master controls and initiates all transfers, but the slave DSPIs use the trigger output signal MTRIG to indicate to the DSPI master that a trigger condition has occurred. When a DSPI slave has a change in data to be serialized it asserts the MTRIG signal to the DSPI master which initiates the transfer. When a DSPI slave has its HT signal asserted it will assert its MTRIG signal thereby propagating trigger signals from other DSPI slaves to the DSPI master.

The DSPI_DSICR0[MTOE] bit must be set in master and all slave devices. The DSPI_DSICR0[MTOCNT] field for the master and all slave devices must be written with the same value. The value must equal the sum of all FMSZ fields in the selected DSPI_CTARs for the DSPI master and all DSPI slaves. For example if one 16-bit DSI frame is created by concatenating eight bits from the DSPI master, and four bits from each of the DSPI slaves in the above figure, the DSPI master frame size must be set to eight in the FMSZ field, and the DSPI slaves frame size must be set to four. The largest DSI frame supported by the MTOCNT field is 64 bits. Any number of DSPIs can be connected together to concatenate DSI frames, as long as each DSPI transfers a minimum of 4 bits and a maximum of 32 bits and the total size of the concatenated frame is less than 65 bits long.

48.4.4 Combined Serial Interface (CSI) configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis. CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. [Figure 775](#) shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

Figure 775. Example of System using DSPI in CSI Configuration

In CSI Configuration the DSPI transfers DSI data based on [Section 48.4.3.5, DSI transfer initiation control](#). When there are SPI commands in the TX FIFO, the SPI data has priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or SPI data is transmitted. The user must configure the DSPI so that the two CTARs associated with DSI data and SPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a SPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

48.4.4.1 CSI serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR selected by the DSICR0[DSICTAS] field.

The parallel inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR) on the rising edge of every protocol clock and serialized based on the transfer initiation control settings in the DSPI_DSICR1/0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty) they have priority over DSI data and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in the DSPI_COMPR1/0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

48.4.4.2 CSI deserialization

The deserialized frames in CSI Configuration goes into the DSPI_DDR1/0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred the returned frames are deserialized and latched into the DSPI_DDR1/0. When SPI frames are transferred the returned frames are deserialized and written to the RX FIFO.

48.4.5 DSPI baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. [Figure 776](#) shows conceptually how the SCK signal is generated.

Figure 776. Communications clock prescalers and scalers

48.4.5.1 Baud rate generator

The baud Rate is the frequency of the Serial Communication Clock (SCK). The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. [Table 820](#) shows an example of how to compute the baud rate.

Table 820. Baud rate computation example

f_p	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

Note: The clock frequencies mentioned in [Table 820](#) are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.4.5.2 PCS to SCK delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Table 821](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTARx registers select the PCS to SCK delay by the formula in the CSSCK field description. [Table 821](#) shows an example of how to compute the PCS to SCK delay.

Table 821. PCS to SCK delay computation example

f_p	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK delay
100 MHz	0b01	3	0b0100	32	0.96 μ s

PCSCSK and CSSCK fields have no effect in TSB configuration.

Note: The clock frequency mentioned in [Table 821](#) is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.4.5.3 After SCK delay (t_{ASC})

The After SCK delay is the length of time between the last edge of SCK and the negation of PCS. See [Table 822](#) for an illustration of the After SCK delay. The PASC and ASC fields in the CTARx registers select the After SCK Delay by the formula in the ASC field description. [Table 822](#) shows an example of how to compute the After SCK delay.

Table 822. After SCK delay computation example

f_p	PASC	Prescaler	ASC	Scaler	After SCK delay
100 MHz	0b01	3	0b0100	32	0.96 μ s

PCASC and ASC fields have no effect in TSB configuration.

Note: The clock frequency mentioned in [Table 822](#) is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.4.5.4 Delay after transfer (t_{DT})

The delay after transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Table 823](#) for an illustration of the delay after transfer. the pdt and dt fields in the CTARx registers select the Delay after Transfer by the formula in the DT field description. [Table 823](#) shows an example of how to compute the delay after transfer.

Table 823. Delay after transfer computation example

f_p	PDT	Prescaler	DT	Scaler	Delay after transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

Note: The clock frequency mentioned in [Table 823](#) is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in non-continuous clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] bitfield description. When in continuous clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on [Section 48.4.9, Timed Serial Bus \(TSB\)](#).

48.4.5.5 Peripheral Chip Select Strobe Enable ($\overline{PCSS}$)

The PCSS signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the DSPI is in master mode and the PCSSE bit is set in the MCR, PCSS provides a signal for an external demultiplexer to decode the PCS[0]–PCS[4] and PCS[6]–PCS[7] signals into as many as 128 glitch-free PCS signals. [Figure 777](#) shows the timing of the PCSS signal relative to PCS signals.

Figure 777. Peripheral Chip Select Strobe Timing

The delay between the assertion of the PCS signals and the assertion of PCSS is selected by the PCSSCK field in the CTAR based on the following formula:

Equation 29
$$t_{PCSSCK} = \frac{1}{f_P} \times PCSSCK$$

At the end of the transfer the delay between $\overline{PCSS}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

Equation 30
$$t_{PASC} = \frac{1}{f_P} \times PASC$$

[Table 824](#) shows an example of how to compute the t_{PCSSCK} delay.

Table 824. Peripheral Chip Select Strobe Assert Computation Example

f_P	PCSSCK	Prescaler	Delay before transfer
100 MHz	0b11	7	70.0 ns

[Table 825](#) shows an example of how to compute the t_{PASC} delay.

Table 825. Peripheral Chip Select Strobe Negate Computation Example

f_P	PASC	Prescaler	Delay after transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK or TSB mode are enabled.

Note: The clock frequency mentioned in the preceding [Table 824](#) and [Table 825](#) is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

48.4.6 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL—Selects the idle state polarity of the SCK
- CPHA—Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in slave mode these values must be identical to the master device settings to ensure proper transmission. In SPI slave mode, only CTAR0 is used.

In DSI slave mode, only CTAR1 is used.

The DSPI supports four different transfer formats:

- Classic SPI with CPHA = 0
- Classic SPI with CPHA = 1
- Modified Transfer format with CPHA = 0
- Modified Transfer format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The DSPI can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the SPI and DSI Configurations, the DSPI provides the option of keeping the PCS signals asserted between frames. See [Section 48.4.6.5, Continuous Selection Format](#) for details.

48.4.6.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in [Figure 778](#) is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

Figure 778. DSPI transfer timing diagram (MTFE = 0, CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

48.4.6.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in [Figure 779](#) is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges

Figure 779. DSPI transfer timing diagram (MTFE = 0, CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

48.4.6.3 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actually sample point is delayed by 1 protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE = 1. Timing delays shown are:

- t_{CSC} – PCS to SCK assertion delay
- t_{ACS} – After SCK PCS negation delay
- t_{su_ms} – master SIN setup time
- t_{hd_ms} – master SIN hold time
- t_{vd_sl} – slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- t_{su_sl} – data setup time on slave data input
- t_{hd_sl} – data hold time on slave data input
- t_p – protocol clock period

Figure 780 shows the modified transfer format for CPHA = 0 and $f_p/f_{sck} = 4$. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behaviors are shown.

- Signal, marked “SOUT of Ext Slave”, presents regular SPI slave serial output.
- Signal, marked “SOUT of DSPI Slave”, presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note: In the following diagrams, f_p represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

Figure 780. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/4$)Figure 781. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/2$)

Figure 782. DSPI Modified Transfer Format (MTFE = 1, CPHA = 0, $f_{sck} = f_p/3$)

48.4.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay must be greater or equal to half of the SCK period.**

Figure 783. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/2$)

Figure 784. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/3$)Figure 785. DSPI Modified Transfer Format (MTFE = 1, CPHA = 1, $f_{sck} = f_p/4$)

48.4.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the SPI Configuration by setting the CONT bit in the SPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0.

The behavior of the PCS signals in the two configurations is identical so only SPI Configuration will be described. When the CONT bit = 0, the DSPI drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The timing diagram in [Figure 786](#) is for

two four-bit transfers with $CPHA = 1$ and $CONT = 0$.

Figure 786. Example of non-continuous format ($CPHA = 1$, $CONT = 0$)

When the $CONT$ bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers.

[Figure 787](#) shows the timing diagram for two four-bit transfers with $CPHA = 1$ and $CONT = 1$.

Figure 787. Example of continuous transfer ($CPHA = 1$, $CONT = 1$)

When using DSPI with continuous selection follow these rules:

- all transmit commands must have the same PCSn bits programming.
- the CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.
- when transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit de-asserted (in master mode) and the user software must provide sufficient frames in the TX_FIFO to be sent out (in slave mode) and the master de-asserts the PCSn at end of transmission of last frame.
- The PUSHHR[CONT]/DSICR0[DCONT] bits must be de-asserted before asserting MCR[HALT] bit (in master mode). This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] bit during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from RUNNING to STOPPED state.

Note: You must fill the TXFIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TXFIFO becomes empty.

When operating in slave mode, ensure that when the last-entry in the TXFIFO is completely transmitted (that is the corresponding TCF flag is asserted and TXFIFO is empty), the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

48.4.6.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to the Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC} , can be masked out and are not inserted by the hardware.

Note: The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed in DSI and CSI configurations or if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing '1' into FCPCS bit of the MCR. When this bit is asserted, MASC and MCSC bits of the PUSHHR perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHHR.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here, too.

Figure 788 shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

Figure 788. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

48.4.7 Continuous Serial Communications Clock

The DSPI provides the option of generating a continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous Serial Communications Clock regardless of the MCR[HALT] bit status. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the DSPI is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the DSPI is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.
- When the DSPI is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
 - At the start of a SPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
 - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the DSPI is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle.

When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles. [Figure 789](#) is the timing diagram for Continuous SCK format with Continuous Selection disabled.

Note: When in Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TXFIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

Figure 789. Continuous SCK timing diagram (CONT = 0)

If the CONT bit in the TX FIFO entry is set or the DCONT in the DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with

PCS asserted, but with no data being shifted out of SOUT (SOUT pulled high). This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the transmit FIFO.
- Continuous SCK with CONT bit set and entering STOPPED state (refer to [Section 48.4.1, Start and Stop of DSPI transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

[Figure 790](#) shows the timing diagram for Continuous SCK format with Continuous Selection enabled.

Figure 790. Continuous SCK Timing Diagram (CONT = 1)

48.4.8 Slave mode operation constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the DSPI is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the SS signal is asserted and any time when transmit data is ready and SS signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR1/0 register.

If the SS negates before that last SCK edge, the data from shift register is lost.

48.4.9 Timed Serial Bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting DSICR0[TSBC] bit. See DSPI DSI Configuration Register 0 (DSPI_DSICR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the device.

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

Figure 791 shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR1/0), written by the host software,
- parallel input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR1/0).

DSICR0[TXSS] bit or DSPI_SSR1/0 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

Figure 791. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

Figure 792. TSB Downstream Frames

[Figure 792](#) shows the two types of MSC downstream frames: command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit “0” indicates a data frame
- The selection bit “1” indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR1/0 or ASDR1/0 registers and up to two zero selection bits. Number of data bits in the data frame is defined by the DSICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI_DSICR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTARn[LSBFE] to transmit least significant bit first.

Regardless of the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before the corresponding data subframes.

48.4.9.1 MSC Dual Receiver Support with PCS Switchover

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switchover occurs, is defined by FMSZ field of the DSPI_CTARn register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSPI_DSICR0 DPCS_n bits, after that by DSPI_DSICR1 DPCS_{1_n} bits.

The PCS switchover occurs at the driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switchover if enabled.

The Data Frame with PCS switchover is shown in [Figure 793](#).

Figure 793. TSB Data Frame Format for MSC Dual Receiver Operation

48.4.10 Interleaved TSB (ITSB) Mode

This mode is similar to the TSB in all aspects except for the differences mentioned in [Table 826](#). In the Interleaved TSB or ITSB mode, frame transmission is governed by the following rules:

- Transmission of frames is done on a periodic trigger that can be generated internal to the DSPI. The trigger period is calculated as follows:
 - Trigger Period = 64 bits (maximum data frame size) + 2 selection bits (maximum bits in data frame) + t_{PT}
 - t_{PT} is the passive frame time or dead time inserted to have constant trigger period.
 - The user software shall configure the trigger period and trigger source.
- If the previously transmitted frame was a SPI frame or the TX FIFO (or CMD FIFO) is empty, the frame transmitted on subsequent trigger will always be a DSI frame.
- If the previously transmitted frame was not a SPI frame and the TX_FIFO (and CMD FIFO) is not empty, the frame transmitted on subsequent trigger will always be a SPI frame.

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) in such a way to prevent back to back SPI frames. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits cannot be asserted).

MCR[MTFE] should be set to 0 during ITSB Mode of operation, since MicroSecond Channel upstream operation is not supported.

[Table 826](#) lists the differences between the TSB and ITSB modes.

Table 826. Differences between TSB and ITSB modes

Mode attribute	TSB mode	ITSB mode
Frame priority	Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Frame selection bit	Selection bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Frame transmission	Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Periodically triggered transmission (that is frames are transmitted continuously on every trigger).
Frame gap	Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is inserted automatically as the whole operation is based on a periodic trigger. If a frame has less than 64-bits to be transmitted, dead or passive time is automatically inserted by waiting for the next trigger pulse. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

However, in both TSB and ITSB mode, separate frame completion interrupts will be available to indicate frame transmission completion from SPI and DSI. MSC dual receiver support with PCS switchover is also supported in ITSB mode. See [Section 48.4.9.1, MSC Dual Receiver Support with PCS Switchover](#) for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the ITSB mode features listed in the table above.

48.4.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] should not be used in ITSB mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.
- Depending on the source of trigger, set the values in the DSICR0[TRG] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame completion (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in [Section 48.4.10, Interleaved TSB \(ITSB\) Mode](#).

48.4.10.2 Using ITSB mode for MSC downstream channel

MSC Downstream Channel uses two types of frames: command frames and data frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- If command frame has less bits than data frame, a gap is inserted to ensure next data frame starts at known reference time.
- In dual MSC ASIC, some bits of the data frame (which can be up to 64 bits) goes to first ASIC and remainder bits to second ASIC.
- In dual MSC ASIC, if a command frame is sent to one ASIC, it must not change the timing of the next data frame.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode (See [Section 48.4.10.1, Configuring DSPI for ITSB mode](#)), the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in [Section 48.4.4, Combined Serial Interface \(CSI\) configuration](#).

[Figure 794](#) shows a sample MSC Downstream transmission using the ITSB mode.

Figure 794. Sample MSC downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, since there are no command frames, a data frame is transmitted: to send a command frame at the start of operation, the user software must program a command frame in the TX_FIFO before enabling DSPI (MCR[HALT] = 0).
- The second trigger sets off the transmission of another data frame.
- Between second and third trigger, two command frames are pushed into the TX_FIFO.
- At third trigger, a command frame is transmitted as the TX_FIFO is not empty: since only 16 bits or less are transmitted, no transmission happens till next trigger. This is marked as the "Passive Time". The passive time is added in all frames after frame transmission completes and until next trigger pulse is detected.
- At fourth trigger, since the previous transmission was a command frame, a data frame is transmitted.
- At fifth trigger, since one command frame is pending in TX_FIFO and last transmitted frame was not a command frame, a command frame is transmitted.
- At sixth trigger (not shown), the process continues.

48.4.11 Parity generation and check

The DSPI module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The register fields setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The DSPI module can be programmed to stop SPI or/and DSI frame transmission in case of a frame reception with parity error.

48.4.11.1 Parity for SPI frames

When the DSPI is in the master mode the parity generation is controlled by PE and PP bits of the TX FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the DSPI stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode, the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

48.4.11.2 Parity for DSI frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI_DSICR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. (DSPI_DSICR0[DCONT] bit has no effect on parity generation. In slave mode, the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSPI_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation, clear the DSPI_SR[DPEF] or the DSPI_DSICR0[PES] bits.

48.4.12 Interrupts/DMA requests

Certain DSPI conditions can generate only interrupt requests and other DSPI conditions can generate either interrupt requests or DMA requests. [Table 827](#) lists these conditions.

Table 827. Interrupt and DMA request conditions

DSPI condition	Flag	Request type	
		Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	—
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	—
Transfer Complete	TCF	Yes	—
CMD Transfer Complete	CMDTCF	Yes	—
SPI Transfer Complete	SPITCF	Yes	—
DSI Transfer Complete	DSITCF	Yes	—
TX FIFO Underflow	TFUF	Yes	—
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	—
SPI Parity Error	SPEF	Yes	—
DSI Parity Error	DPEF	Yes	—
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a flag bit in the DSPI Status Register (SR) and a Request Enable bit in the DSPI DMA/Interrupt Request Select and Enable Register (RSER). The TX FIFO Fill Flag (TFFF) and RX FIFO Drain Flag (RFDF) generate interrupt requests or DMA requests depending on the TFFF_DIRS and RFDF_DIRS bits in the RSER.

The DSPI module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

48.4.12.1 End of Queue interrupt request

The End of Queue Request indicates that the end of a transmit queue is reached. The End of Queue Request is generated when the EOQ bit in the executing SPI command is set and the EOQF_RE bit in the RSER is set.

When MCR[XSPI] is enabled and the EOQ bit in the executing SPI command is set, the End of Queue Request will only be generated once the last Data frame in the Command Cycle has been transmitted.

Note: This interrupt request is generated when the last bit of the SPI frame with EOQ bit set is transmitted.

48.4.12.2 Transmit FIFO Fill interrupt or DMA request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

Note: TFFF flag clears automatically when DMA is used to fill TXFIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TXFIFO:

- Wait until TFFF = 1
- Write data to PUSHR using CPU.
- Clear TFFF by writing a '1' to its location. If TX FIFO is not full, this flag will not clear.

48.4.12.3 Command FIFO Fill interrupt or DMA request

The Command FIFO Fill Request indicates that the CMD FIFO is not full. The Command FIFO Fill Request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the CMDFFF_RE bit in the RSER is set. The CMDFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

This Request is useful when MCR[XSPI] is enabled and hence TX FIFO and CMD FIFO can be filled independently. If MCR[XSPI] is disabled, then 'TX FIFO Fill Interrupt or DMA Request' will suffice to fill both FIFO's since both FIFO's must be filled simultaneously.

Note: CMDFFF flag clears automatically when DMA is used to fill CMD FIFO.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

- Wait until CMDFFF = 1
- Write data to Command field of PUSHR using CPU.
- Clear CMDFFF by writing a '1' to its location. If CMD FIFO is not full, this flag will not clear.

48.4.12.4 Transmit FIFO Invalid Write interrupt request

The Transfer Fifo Invalid Write Request is valid only when MCR[XSPI] is enabled. This Request indicates that Data exists in the TX FIFO while the CMD FIFO is empty. Since no Command Fields are associated with the Data present in TX FIFO, this data is considered invalid until a Command Entry becomes available. The Transfer Fifo Invalid Write Request is generated for the above condition when TFIWF_RE bit is set in the RSER.

48.4.12.5 Transfer Complete interrupt request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

48.4.12.6 Command Transfer Complete interrupt request

The Command Transfer Complete Request indicates the end of transfer of the last SPI frame in a Command Cycle. The Transfer Complete Request is generated for the above condition when the CMDTCF_RE bit is set in the RSER.

48.4.12.7 SPI Transfer Complete interrupt request

The SPI Transfer Complete Request indicates the end of transfer of an SPI frame in any Transmission Mode which uses DSPI in CSI Mode. The SPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

48.4.12.8 DSI Transfer Complete interrupt request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

48.4.12.9 Transmit FIFO Underflow interrupt request

The Transmit FIFO Underflow request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the DSPI, operating in slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of a DSPI is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

48.4.12.10 Receive FIFO Drain interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

48.4.12.11 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

48.4.12.12 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

48.4.12.13 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

48.4.12.14 Deserialized Data Match Interrupt or DMA Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI_DPIR1/0 data, masked with DSPI_DIMR1/0, has been received. This Request is generated if DDIF_RE bit in the DSPI_RSER is set. The DDIF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

48.4.13 Power saving features

The DSPI supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory-mapped logic

48.4.13.1 Stop mode (External Stop Mode)

The DSPI supports the stop mode protocol. When a request is made to enter external stop mode, the DSPI block acknowledges the request. If a serial transfer is in progress, the DSPI waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, the DSPI memory-mapped logic is not accessible. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

48.4.13.2 Module disable mode

Module disable mode is a block-specific mode that the DSPI can enter to save power. The host CPU can initiate the module disable mode by setting the MDIS bit in the MCR. The module disable mode can also be initiated by hardware. A power management block can initiate the module disable mode by asserting the DOZE mode signal while the DOZE bit in the MCR is set.

When the MDIS bit is set or the DOZE mode signal is asserted while the DOZE bit is set, the DSPI negates Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, DSPI is said to have entered Module Disable Mode. This also puts the DSPI in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory-mapped logic. When Clock Enable is negated, the DSPI is in a dormant state, but the memory-mapped registers are still accessible. Certain read or write operations have a different effect when the DSPI is in the module disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Likewise, writing to the FIFO Push Register does not change the state of the TX FIFO or CMD FIFO. Clearing of the FIFOs has no effect in the module disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the module disable mode. In the module disable mode, all status bits and register flags in the DSPI return the correct values when read, but writing to them has no effect. Writing to the TCR during module disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the module disable mode.

48.5 Initialization/application information

This section describes how to initialize the DSPI module.

48.5.1 Managing DSPI queues

The queues are not part of the DSPI, but the DSPI includes features in support of queue management. Queues are primarily supported in SPI Configuration.

1. When DSPI executes last command word from a queue, the EOQ bit in the command word is set to indicate to the DSPI that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the DSPI in the STOPPED state. The TXRXS bit is cleared to indicate the STOPPED state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DSPI DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a '1' to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the DSPI TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

48.5.2 Switching master and slave mode

When changing modes in the DSPI, follow the steps below to guarantee proper operation.

1. Halt the DSPI by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a '1' to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable the DSPI by clearing MCR[HALT].

48.5.3 Initializing DSPI in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the DSPI is enabled by clearing MCR[HALT]. It should be ensured that DSPI Slave is enabled before enabling DSPI Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

48.5.4 Baud rate settings

[Table 828](#) shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is clear.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the clocking chapter for the frequency used to drive this module in the device.

Table 828. Baud rate values (bps)

		Baud rate divider prescaler values (DSPI _n _CTAR[PBR])			
		2	3	5	7
Baud Rate scaler values (DSPI _n _CTAR[BR])	2	25.0 MHz	16.7 MHz	10.0 MHz	7.14 MHz
	4	12.5 MHz	8.33 MHz	5.00 MHz	3.57 MHz
	6	8.33 MHz	5.56 MHz	3.33 MHz	2.38 MHz
	8	6.25 MHz	4.17 MHz	2.50 MHz	1.79 MHz
	16	3.12 MHz	2.08 MHz	1.25 MHz	893 kHz
	32	1.56 MHz	1.04 MHz	625 kHz	446 kHz
	64	781 kHz	521 kHz	312 kHz	223 kHz
	128	391 kHz	260 kHz	156 kHz	112 kHz
	256	195 kHz	130 kHz	78.1 kHz	55.8 kHz
	512	97.7 kHz	65.1 kHz	39.1 kHz	27.9 kHz
	1024	48.8 kHz	32.6 kHz	19.5 kHz	14.0 kHz
	2048	24.4 kHz	16.3 kHz	9.77 kHz	6.98 kHz
	4096	12.2 kHz	8.14 kHz	4.88 kHz	3.49 kHz
	8192	6.10 kHz	4.07 kHz	2.44 kHz	1.74 kHz
	16384	3.05 kHz	2.04 kHz	1.22 kHz	872 Hz
	32768	1.53 kHz	1.02 kHz	610 Hz	436 Hz

48.5.5 Delay settings

[Table 829](#) shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (t_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

Note: The protocol clock frequency mentioned above is given as an example in this chapter. Refer to the clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

Table 829. Delay values

		Delay prescaler values (DSPIn_CTAR[PBR])			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 μ s
	32	320.0 ns	960.0 ns	1.6 μ s	2.2 μ s
	64	640.0 ns	1.9 μ s	3.2 μ s	4.5 μ s
	128	1.3 μ s	3.8 μ s	6.4 μ s	9.0 μ s
	256	2.6 μ s	7.7 μ s	12.8 μ s	17.9 μ s
	512	5.1 μ s	15.4 μ s	25.6 μ s	35.8 μ s
	1024	10.2 μ s	30.7 μ s	51.2 μ s	71.7 μ s
	2048	20.5 μ s	61.4 μ s	102.4 μ s	143.4 μ s
	4096	41.0 μ s	122.9 μ s	204.8 μ s	286.7 μ s
	8192	81.9 μ s	245.8 μ s	409.6 μ s	573.4 μ s
	16384	163.8 μ s	491.5 μ s	819.2 μ s	1.1 ms
	32768	327.7 μ s	983.0 μ s	1.6 ms	2.3 ms
	65536	655.4 μ s	2.0 ms	3.3 ms	4.6 ms

48.5.6 Calculation of FIFO pointer addresses

Complete visibility of the TX and CMD and RX FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and a memory-mapped counter for each FIFO. The pointer to the first-in entry in each FIFO is memory-mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). [Figure 795](#) illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over to the CMD FIFO and RX FIFO. See [Section 48.4.2.4, Transmit First In First Out \(TX FIFO\) buffering mechanism](#), [Section 48.4.2.5, Command First In First Out \(CMD FIFO\) buffering mechanism](#) and [Section 48.4.2.6, Receive First In First Out \(RX FIFO\) Buffering Mechanism](#) for details on the FIFO operation.

Figure 795. TX FIFO pointers and counter

48.5.6.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{Equation 31} \quad \text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Equation 32} \quad \text{Last-in EntryAddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base – Base address of TX FIFO

TXCTR – TX FIFO Counter

TXNXPTR – Transmit Next Pointer

TX FIFO Depth – Transmit FIFO depth, implementation specific

48.5.6.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{Equation 33} \quad \text{First-in EntryAddress} = \text{CMDFIFOBase} + (4 \times \text{CMDNXPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

Equation 34 Last-in

$$\text{EntryAddress} = \text{CMDFIFOBase} + 4 \times (\text{CMDCTR} + \text{CMDNXTPTR} - 1) \bmod(\text{CMDFIFOdepth})$$

CMD FIFO Base – Base address of CMD FIFO

CMDCTR – CMD FIFO Counter

CMDNXTPTR – Command Next Pointer

CMD FIFO Depth – Command FIFO depth, implementation specific

48.5.6.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

Equation 35 First-in
$$\text{EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

Equation 36 Last-in
$$\text{EntryAddress} = \text{RX FIFOBase} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod(\text{RXFIFOdepth})$$

RX FIFO Base – Base address of RX FIFO

RXCTR – RX FIFO counter

POPNXTPTR – Pop Next Pointer

RX FIFO Depth – Receive FIFO depth, implementation specific

49 LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

49.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

49.2 Block diagram

Figure 796 depicts LFAST interaction with other modules on the device.

Figure 796. LFAST block diagram

49.3 External signals

LFAST is a five pin interface with the following signals:

- lfast_sysclk
 - Reference clock of the LFAST master and slave
- txdatap/txdatan
 - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
 - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface with maximum data rate of 320 Mbps.

49.3.1 LFAST operating data rates

[Table 830](#) shows the operating modes for the LFAST interface.

Table 830. Operating modes for LFAST interface

Interface	Tx/Rx Data Rate
LFAST Transmit	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps
LFAST Receive	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps ($\text{lfast_sysclk} \div 4$ or $\text{lfast_sysclk} \div 2$) is referred to as low and data rates 312 Mbps and 320 Mbps is referred to as high data rates.

49.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.

A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See [Figure 797](#) for details of the LFAST frame.

Figure 797. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 798. Serial frame structure

The frame structure is shown in [Figure 798](#) and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to [Table 831](#).

Table 831. Header payload sizes

b7-b5 (bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	—	—
111	288	312

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

49.5 Features

- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer rates up to a maximum of 320 Mbps
- Transmits and receives data, CTS, ICLC and unsolicited frames.
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation in slave mode.
- Supports for detection of unsupported channel number and unsupported payload size.

49.6 Memory map and register definition

All registers are 32 bits wide.

49.6.1 Memory map

Table 832. LFAST memory map

Offset from LFAST_BASE (hex)	Register	Access	Reset Value (hex)	Location

The conventions in [Figure 799](#) and [Table 833](#) serve as a key for the register summary and individual register diagrams.

Figure 799. Key to Register Fields

Always reads 1	1	Always reads 0	0	R/W bit	BIT	Read-only bit	BIT	Write-only bit	BIT	Write 1 to clear	BIT w1c	Self-clear bit	0 BIT
----------------	----------	----------------	----------	---------	------------	---------------	------------	----------------	------------	------------------	----------------	----------------	--------------

[Table 833](#) provides a key for register figures and tables and the register summary.

Table 833. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bits value (other than a hardware reset).
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but its cleared by the H/W once the operation defined by the bit is over
Reset Values	
0	Resets to zero.
1	Resets to one.
[signal_name]	Reset value is determined by polarity of indicated signal.

49.6.2 Register descriptions

49.6.2.1 Mode Configuration Register (MCR)

Figure 800. Mode Configuration Register (MCR)

Offset: 0000h								Access: User read/write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

1. Set by user software and cleared by system hardware.
2. Writable only once after the asynchronous reset.
3. Only writable when MCR[DRFEN] = 0.

Table 834. MCR field descriptions

Bits	Description
0 MSEN	LFAST Master or Slave mode Enable. This bit selects either the LFAST master or slave functionality. This bit can be written only once after the asynchronous reset. 0 Enable the modules LFAST Slave functionality only. 1 Enable the modules LFAST Master functionality only.
1-6	Reserved
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8-14	Reserved
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode. Refer to Section 49.10.2, Slow speed clock for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.

Table 834. MCR field descriptions (continued)

Bits	Description
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Transmitter is Enabled.
19-26	Reserved
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 CTSEN	CTS Enable. This bit defines the Push-Pull mode of the LFAST devices receiver. This bit is used to enable/disable CTS mode of the Tx block. 0 CTS mode is disabled. Indicates that the device is in Push mode. The CTS bit of frames transmitted is 1. The CTS bit does not represent the status of Rx FIFO. 1 CTS mode is enabled. The CTS bit of all transmit frames is set when the Rx FIFO empty space is on or above higher threshold, and cleared when the Rx FIFO empty space is on or below lower threshold.
29	Reserved
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

49.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Figure 801. Speed Control Register (SCR)

Offset: 0004h								Access: User read/write									
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DRMD ⁽¹⁾
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	
R	0	0	0	0	0	0	0	RDR	0	0	0	0	0	0	0	TDR	
W																	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

1. Only writable when MCR[DRFEN] = 0.

Table 835. SCR field descriptions

Bits	Description
0-14	Reserved
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. 0 S/W controls the Data Rate controller mode. In LFAST Slave the ICLC frames for rate change have no effect on the Data rate. 1 In LFAST Slave the reception of ICLC frame for rate change sets appropriate speed mode. In LFAST Master the SCR[DRMD] should be 0.
16 - 22	Reserved
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. For LFAST Master: – S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Tx interface. For LFAST Slave: – When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Rx interface. – The S/W can program this bit when SCR[DRMD] = 0. – This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is 312/320 Mbps.

Table 835. SCR field descriptions (continued)

Bits	Description
24-30	Reserved
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. For LFAST Master: – The S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Rx interface. For LFAST Slave: – When SCR[DRMD] = 1, the H/W writes this bit on receipt of an ICLC frame changing the speed mode of the slaves Tx interface. – The S/W can program this bit when SCR[DRMD] = 0. – This bit is cleared on MCR[DRFEN] = 0. 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is 312 /320 Mbps.

49.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Figure 802. Correlator Control Register (COCR)

Offset: 0008h				Access: User read/write															
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Only writable when MCR[DRFEN] = 0.

1. Only writable when MCR[DRFEN] = 0.

Table 840. SLCR field descriptions

Bits	Description
0-7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. 00h 0 cycle 01h 1 cycle ... 12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8-11	Reserved
0-15	Reserved
12-15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles
16-23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. 00h0 cycles 01h1 cycle ... 5Fh95 cycles (1.18 us) ... FFh255 cycles Maximum
24-27	Reserved
28-31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. 0h0 cycle 1h1 cycle 2h2 cycles (1.18 us) ... Eh14 cycles Fh15 cycles

49.6.2.8 ICLC Control Register (ICR)

Figure 807. ICLC Control Register (ICR)

1. Writable only when ICR[SNDICLC] = 0
2. Set by user software and cleared by system hardware.

Table 841. ICR field descriptions

Field	Description
0-13	Reserved
14 ICLCSEQ	ICLC enabled. This bit should be set whenever the S/W is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frames request are ignored. 1 S/W is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0. 0 Single ICLC frame transfer
15 SNDICLC	ICLC frame request. This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. 1 Valid ICLC frame for transfer. 0 No Valid ICLC frame for transfer.
16-23	Reserved
24-31 ICLCPLD	ICLC Payload. This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. Refer to Table 867 for supported ICLC payloads.

49.6.2.9 Ping Control Register (PICR)

Figure 808. Ping Control Register (PICR)

Offset: 0020h Access: User read/write

1. Only writable when MCR[DRFEN] = 0.

2. Set by user software and cleared by system hardware.

Table 842. PICR field descriptions

Bits	Description
0-14	Reserved
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master 0 Ping response should not be automatically sent. 1 Ping response should be automatically sent.
17-23	Reserved
24-31 PNGPYLD	LFAST Slave: Defines the LFAST slaves ping reply frame payload content. LFAST Master: Defines the expected payload of ping response frame. Used for comparison with ping frame received.

49.6.2.10 Rx FIFO CTS Control Register (RFCR)

24-28	Reserved
29-31 URPCNT	Rx Unsolicited payload. Indicates the number of bytes of valid Rx unsolicited data payload present in the Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0). The bitfield coding is same as b7-b5 in Table 831 .

49.6.2.26 Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0)

Figure 825. Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0)

Table 859. UNSRDRn field descriptions

Bits	Description
0-31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data. It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

49.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements⁽ⁿ⁾. All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

n. See the "Functional Safety" chapter for register classification details.

49.7 Functional description

49.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

49.7.1.1 LFAST master interface startup procedure

1. After reset the SLCR and RCDCCR are programed according to the LVDS parameters in the device datasheet.
2. The PLLCR is programmed with configuration parameters for the PLL.
3. The LCR is programed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. Write ICR[SNDICLC] = 1 and ICR[ICLCSEQ] = 1.
9. Write MCR[TXARBD] = 0.
10. The ICLC transmission is confirmed by verifying one of the following:
 - ICR[SNDICLC] = 0.
 - TISR[TXICLCF] = 1.
11. Write ICR[ICLCPLD] = 00h to check the LFAST slaves status.
12. Write ICR[SNDICLC] = 1.
13. The LFAST slave status is confirmed by occurence of one of the following:
 - LFAST slave is enabled if RIISR[ICPSF] = 1. Proceed to step 14.
 - LFAST slave is disabled if RIISR[ICPFF] = 1. The LFAST master must wait and restart from Step 7.

Speed mode change:

14. Write LCR[SWPON] = 1 to enable the LFAST masters PLL.
15. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
16. Write ICR[SNDICLC] = 1.
17. The ICLC transmission is confirmed by occurrence of one of the following:
 - ICR[SNDICLC] = 0.
 - TISR[TXICLCF] = 1.
18. To change LFAST masters Tx interface speed both of the following operations are performed:
 (Note: The slaves Rx interface speed should be changed first.)
 - Write ICR[ICLCPLD] = 10h for Tx data fast frame.
 - Write ICR[SNDICLC] = 1.
19. Both of the following operations are performed to change the LFAST masters Rx interface speed:
 (Note: The slaves Tx interface speed mode should be changed first)
 - Write ICR[ICLCPLD] = 80h to select Rx data fast frame.
 - Write ICR[SNDICLC] = 1.
20. The ICLC transmission is confirmed by the occurrence of one of the following:
 - ICR[SNDICLC] = 0
 - TISR[TXICLCF] = 1.
21. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.
22. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.
23. Write ICR[ICLCPLD] = 00h to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.
24. Write ICR[SNDICLC] = 1
25. Write MCR[TXARBD] = 1, after some delay to ensure the step 24 ICLC frame is send but no other frame is sent to arbitration.
26. The LFAST slaves speed mode is confirmed by the occurrence of the following:
 - If RIISR[ICPSF] = 1. The LFAST slave is in High Speed mode.
 - If RIISR[ICPFF] = 1. The LFAST slave is in Low Speed mode.
27. If RIISR[ICPSF] = 1, then all frame arbitration is enabled by both of the following operations:
 - Write ICR[ICLCSEQ] = 0.
 - Write MCR[TXARBD] = 0.
28. If RIISR[ICPFF] = 1 modifying the LFAST slaves speed needs to be repeated by:
 - Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
 - Write MCR[TXARBD] = 0, to enable frame transmission.
 - The operations from step 14 need to be executed again.

49.7.1.2 LFAST slave interface startup procedure

1. After reset the SLCR and RCDCCR are programed according to the LVDS parameters in the device datasheet.
2. The PLLCR is programed with the configuration parameters for the PLL.
3. The LCR is programed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signal and LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following are true:
 - When an ICLC frame with payload 31h is received the H/W will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
 - MCRMCR[TXEN] = 1
8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
 - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h frame is received.H/W writes [ICRPF] = 1
 - PICR[PNGREQ] = 1.

Speed mode change:

9. The PLL will start when one of the following conditions is met:
 - When an ICLC frame with payload 02h is received. H/W writes RIISR[IPONF] = 1
 - Write PLLCR[SWPON] = 1.
10. The speed of the Tx interface is changed on one of the following conditions:
 - When SCR[DRMD] = 1 and an ICLC frame with payload 80h is received. H/W writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
 - SCR[TDR] = 1 when SCR[DRMD] = 0
11. The speed of the Rx interface is changed on one of the following conditions:
 - When SCR[DRMD] = 1 and an ICLC frame with payload 10h is received. H/W writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
 - SCR[RDR] = 1, when SCR[DRMD] = 0
12. A Ping Frame is sent on one of the following conditions:
 - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h is received.H/W writes RIISR[ICRPF] = 1
 - Write PICR[PNGREQ] = 1.

49.7.2 Line Receiver (LR)

49.7.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling

edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 826 shows the block diagram of Uplink Controller.

Figure 826. Top Level Receive Controller

49.7.2.2 Edge-Detection & Auto correlation

The edge-detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

49.7.2.2.1 Auto correlation modes

49.7.2.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the

synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 827. Hunt Correlation mode

49.7.2.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

49.7.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in [Figure 828](#).

Figure 828. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in [Figure 829](#).

Figure 829. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in [Figure 830](#) and [Figure 831](#).

Figure 830. High Speed 4 Phase Clock Alignment Example

Figure 831. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed (312/320 MHz) 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to an intermediate phase as shown in [Table 860](#), [Table 861](#), and [Table 862](#) before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 860. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0

6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See [Table 861](#), Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 862. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See [Table 862](#), Samplers 4, 5, 6, 7 are disabled. The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

49.7.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in [Figure 832](#).

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (e.g Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

Figure 832. Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in [Figure 833](#).

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

Figure 833. Sampler 5 Logic

49.7.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in [Figure 834](#)

Figure 834. Extracting Header and Payload from the 16-bit output from Auto correlation.

49.7.2.3.1 Line Receiver states

The LD has the following states:

- Shutdown**
The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a Vdd level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep**
The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- **Normal**
In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 863. Line Receiver State

LR State	LFAST Master Triggers (at least one of the following)	LFAST Slave Triggers (at least one of the following)
Shutdown	– Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]	– LFAST interface enable assertion/negation – Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LCR[SWWKLR]	– Programing of LCR[SWSLPLR] or LCR[SWWKLR]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

49.7.3 Transmit Controller

49.7.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, CTS, ping etc. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Recieve Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in [Figure 835](#).

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 835. Transmit Controller Connections

49.7.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- S/W programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in [Table 864](#).

Table 864. Priority Levels for the Transmit Controller

Request	LFAST Master Priority	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
LFAST interface enable	1	1	– LFAST interface enable is asserted – LFAST interface enable is negated
Tx Interface disabled	2	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

Table 864. Priority Levels for the Transmit Controller

Request	LFAST Master Priority	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
Tx Interface speed mode change	3	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received <i>Note:</i> Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
ICLC frame request	5	–	– LFAST Master: ICR[SNDICLC] = 1 – LFAST Master: ICR[ICLCSEQ] = 1
Ping response request	–	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	6	– Last Frame with CTS = 1 received from the peer LFAST device – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	7	– Tx FIFO contains one or more frames – Last Frame with CTS = 1 received from the peer LFAST device – MCR[DATAEN] = 1
CTS Frame	8	8	– MCR[CTSEN] = 1 – Rx FIFO reaches High/Low threshold, defined by TISR and no frame pending
Clock mode test	9	9	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCCR[DRCNT].

49.7.3.3 Line Driver digital connections

49.7.3.3.1 Line Driver states

The LD has the following states:

- Shutdown**
The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication. The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.
- Sleep**
The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to V_{cm} (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a predefined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

Figure 836. Example of Sleep mode

As shown in [Figure 836](#) before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal**
In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. If the LD is not enabled, and the framer is activated, and has a frame to transmit, an interrupt (TISR[TXIEF]) will be generated. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 865. Line Driver States

LD State	LFAST Master Triggers	LFAST Slave Triggers
Shutdown	– Programing LVDS[SWOFFLD] and LVDS[SWONLD] – Programing MCR[TXEN] and MCR[DRFEN]	– LFAST interface enable negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

49.7.4 CTS mode support

LFAST module supports flow control method defined in the LFAST3G standard. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write MCR[CTSEN] = 1 then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device does not want the peer device to send data. The CTS bit of all frame are sent 0 until the Rx FIFO pointer reaches the lower threshold, as described below.
- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 until the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frame sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

CTS Reception:

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed until a frame with CTS bit 1 is received.

Figure 837. CTS generation

49.7.5 Frames supported

Table 866 provides the frames supported and their permissible payload sizes

Table 866. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload Size (bits)
Data Frame	0100b – 1011b	YES	YES	32, 64, 96, 128, 256, 288
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO ⁽¹⁾	8
CTS Frame	0011b	YES	YES	8
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

If logical channel type (LCT) code other than the above mentioned are received then the interrupt flag RISR[RXLCEF] = 1. If the payload size received does not match any value in Table 866 then the flag RISR[RXSZF] = 1. In both these error conditions the received frame is ignored. The S/W may have to take the necessary steps to recover from such an error.

49.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

49.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

49.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO. Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

49.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTE] = 1 after each frame transfer.
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

49.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[TXEN] and MCR[DRFEN] bits should be set to enable the data frame reception. When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

49.7.6.2 Unsolicited flow**49.7.6.2.1 Unsolicited frame transmit flow**

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

49.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
 - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
 - UNSTCR[USNDRQ] = 0
 - TISR[TXUNSF] = 1.
 - If UNSTCR[USNDRQ] = 0 then:
 - Program the unsolicited payload in UNSTD0–UNSTD8, and can be written up to a payload of frame of a maximum of 288 bits.
 - Program the unsolicited frame header in UNSTCR[UNSHDR].
 - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

49.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTD0–UNSTD8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

49.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

49.7.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see [Table 867](#) for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

Table 867. Supported ICLC Payloads

ICLC Code (hex)	ICLC Function
00	Ping Request from LFAST Master to LFAST Slave
01	Reserved
02	Start PLL In preparation for High Speed mode
04	Stop PLL Fallback to low speed mode
08	Select TxData Slow (LFAST Slave Rx Interface)
10	Select TxData Fast (LFAST Slave Rx Interface)
20	Select RxData Slow (LFAST Slave Tx Interface)
40	Not Supported
80	Select RxData Fast (LFAST Slave Tx Interface)
31	Enable RxData Interface (LFAST Slave Tx Interface)
32	Disable RxData Interface (LFAST Slave Tx Interface)
34	Clock Test mode Send 101010... continuously using the currently configured clock rate (slow, fast);
FF	Turn payload loopback on
38	Turn Test mode (Loopback and Clock Test) off

Programing model for ICLC frame transmit:

1. Set the ICR[ICLCSEQ] bit (optional).
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the [Table 867](#).
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exist.

Note: ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in [Table 867](#).

49.7.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in [Table 867](#) will cause RISR[RXICF] = 1.

49.7.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

49.7.6.3.2.2 Start PLL ICLC

The Start PLL ICLC command will write bit RIISR[ICPONF] = 1.

49.7.6.3.2.3 Stop PLL ICLC

The Stop PLL ICLC command will write RIISR[ICPOFF] = 1.

49.7.6.3.2.4 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

49.7.6.3.2.5 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

49.7.6.3.2.6 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

49.7.6.3.2.7 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

49.7.6.3.2.8 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

49.7.6.3.2.9 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable .

49.7.6.3.2.10 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

49.7.6.4 CTS flow

49.7.6.4.1 CTS Tx flow

The CTS frame, if enabled by the S/W, indicates the status of the Recieve Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

49.7.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frame with LCT type CTS are not stored in the LFAST.

49.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

49.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 868. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

49.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when

the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 838. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs `TMCR[LPMOD] = 000b`.
2. Loopback can be turned on by either of the following methods:
 - S/W programs `TMCR[LPON] = 1`.
 - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs `TMCR[LPON] = 0`
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

49.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 839. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs `TMCR[LPMOD] = 001b`.
2. Loopback can be turned ON by either of the following methods:
 - S/W writes `TMCR[LPON] = 1`.
 - For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs `TMCR[LPON] = 0`.
- For LFAST Slave:
 - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.

49.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 840. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

49.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 841. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

49.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

When **TMCR[LPMOD] = 011b** (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

Figure 842. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from the LFAST Master.

Exit from Tx Loopback with Automatic frame generation mode can be done by the following method:

- S/W programs TMCR[LPON] = 0.

49.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 843. Tx LVDS Loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by the following method:

- S/W programs TMCR[LPON] = 0.

49.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 34h (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by any of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master.

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

49.7.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC receive interrupt

Each interrupt is asserted when any one of their status conditions is met.

49.7.8.1 Transmit complete interrupt

This interrupt indicates a transfer completion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

49.7.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

Table 869. Recommended transmit exception handling

Exception	Recommendation
TXOVF	– MCR[TXEN] = 0 – The system level interfaces transmit is reseted and enabled again – For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set – For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent
TXIEF	– The MCR[TXEN] should be set

49.7.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

49.7.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

Table 870. Recommended receive exception handling mechanism

Exception	Recommendation
RXLCEF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXICF	No action required
RXSZF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXOFF	– The MCR[RXEN] may be cleared – The system level interfaces receive may be reset and enabled, as current transfer may be corrupted
RXUFF	No action required
RMXF	The system level interfaces receive should be enabled, if not enabled
RXMNF	No action required
RXUNSF	No action required

49.7.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

49.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has its own dedicated buffer, and they are not shared between each other.

Table 871. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer (in bits)	Rx Buffer (in bits)	Memory Type
Data Frame	38 × 32 max 6 packets	38 × 32 max 6 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	1 × 7 max 1 packet ⁽¹⁾	1 × 8 max 1 packet ⁽²⁾	Registers ICR, PISR
CTS Frame	N/A	N/A	N/A

1. Only for MCR[MSEN] = 1

2. Only for ping response data when MCR[MSEN] = 1

49.9 Resets

The various blocks in LFAST are reset as described in [Table 872](#).

Table 872. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]

49.10 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock, used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

49.10.1 Clocking strategy

[Figure 844](#) shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 844. LFAST module clock domains

49.10.2 Slow speed clock

49.10.2.1 External muxing

The Clock Control Module will receive `lfast_sysclk` from the clocking subsystem as shown in [Figure 845](#), [Figure 846](#) and [Figure 847](#).

Figure 845. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in [Figure 845](#).

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 846](#) (selected clock path shown in green).

Figure 846. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, `lfast_sysclk` is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency $\text{lfast_sysclk}/2$ when `MCR[LSSEL] = 0`. If `lfast_sysclk` is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 847](#) (selected clock path selected shown in magenta).

Figure 847. External clock muxing of lfast_sysclk of 10 MHz

49.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. [Figure 848](#) Shows 4 phases getting generated using lfast_sysclk.

Figure 848. Slow speed 4 phases generation

49.10.3 Rx controller clocks

49.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in [Figure 849](#).

Figure 849. Clock Enables and Clock Paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

49.10.3.2 Clock module requirements for low speed phases

49.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq $\times$ 8 MHz clock from the PLL is not needed.

Table 873. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

49.10.4 Tx controller clocks

49.10.4.1 Clocking module requirements for speed phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See [Table 874](#).

Table 874. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

49.10.4.2 Transmit clock muxing

Figure 850. Transmit Clocks Muxing

49.10.4.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

50 Fast Ethernet Controller (FEC)

50.1 Introduction

The Fast Ethernet Controller (FEC) is a communication controller that supports 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports five different standard MAC-PHY (physical) interfaces for connection to an external Ethernet transceiver. The FEC supports the 10/100 Mbps MII, 10/100 Mbps reduced MII, and the 10 Mbps-only 7-wire interface.

50.1.1 Block diagram

[Figure 851](#) shows the block diagram of the FEC. The FEC is implemented with a combination of hardware and microcode. The off-chip (Ethernet) interfaces are compliant with industry and IEEE 802.3 standards.

Figure 851. FEC block diagram

Table 875 provides a brief description of the blocks in Figure 851.

Table 875. FEC sub-block descriptions

Block	Description
Control and status registers (CSR)	Provides global control (Ethernet reset and enable) and interrupt managing registers
Descriptor controller	A RISC-based controller providing these functions in the FEC: – Initialization (those internal registers not initialized by you or hardware) – High-level control of the DMA channels (initiating DMA transfers) – Interpreting buffer descriptors – Address recognition for receive frames – Random number generation for transmit collision backoff timer
DMA block	Provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to all run independently <i>Note: In this document, "DMA" refers to the DMA block within the FEC, and is not related to any other DMA controllers that may be present on the chip.</i>
Media independent interface (MII)	Provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of: – The management data clock (FEC_MDC) – The management data input/output lines (FEC_MDIO) of the MII interface
Message information block (MIB)	Maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC, but provides valuable counters for network management. The counters supported are: – The RMON (RFC 1757) Ethernet Statistics group – Some of the IEEE 802.3 counters See the memory map for more information.
RAM	Serves as the focal point of all data flow in the Fast Ethernet controller and divides into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register. User data flows to/from the DMA block from/to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO into the transmit block. Receive data flows from the receive block into the receive FIFO.
Transmit and receive blocks	Provide the Ethernet MAC functionality (with some assist from microcode)

50.1.2 Features

The FEC incorporates the following features:

- Support for the following Ethernet physical interfaces:^(o)
 - 100-Mbps IEEE 802.3 MII
 - 10-Mbps IEEE 802.3 MII
 - 100-Mbps reduced media independent interface (RMII)
 - 10-Mbps reduced media independent interface (RMII)
 - 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200 Mbps throughput) with a minimum internal bus clock rate of 50 MHz
- Support for half-duplex operation (100 Mbps throughput) with a minimum internal bus clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
 - Frames with broadcast address may be always accepted or always rejected
 - Exact match for single 48-bit individual (unicast) address
 - Hash (64-bit hash) check of individual (unicast) addresses
 - Hash (64-bit hash) check of group (multicast) addresses
 - Promiscuous mode

50.2 Modes of operation

This section describes the FEC operating modes.

50.2.1 Full and half duplex operation

Full duplex mode is for use on point-to-point links between switches or end node to switch. Half duplex mode works in connections between an end node and a repeater or between repeaters. TCR[FDEN] controls duplex mode selection.

When configured for full duplex mode, flow control may be enabled. For more details, see:

- The RFC_PAUSE and TFC_PAUSE fields in the TCR ([Section 50.4.10, Transmit Control Register \(TCR\)](#))
- The RCR[FCE] field ([Section 50.4.9, Receive Control Register \(RCR\)](#))
- [Section 50.5.13, Full duplex flow control](#)

^o. Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.

50.2.2 Interface options^(p)

The following interface options are supported. A detailed discussion of the interface configurations is provided in [Section 50.5.8, Network interface options](#).

50.2.2.1 10 Mbps and 100 Mbps MII interface

The IEEE 802.3 standard defines the media independent interface (MII) for 10/100 Mbps operation. The MAC-PHY interface may be configured to operate in MII mode by programming RCR[MII_MODE] = 1.

The operation speed is determined by the FEC_TXCLK and FEC_RXCLK pins driven by the external transceiver. The transceiver auto-negotiates the speed or software controls it via the serial management interface (FEC_MDC/FEC_MDIO pins) to the transceiver. Refer to the MMFR and MSCR register descriptions, as well as the section on the MII, for a description of how to read and write registers in the transceiver via this interface.

50.2.2.2 10 Mbps and 100 Mbps RMII interface

The reduced media independent interface (RMII) is a low-cost alternative to the IEEE 802.3 MII standard. This interface provides the functionality of the MII interface on a total of 8 pins instead of 18. The RMII interface for 10/100 Ethernet MAC-PHY interface was defined by an industry consortium and is not currently included in the IEEE 802.3 standard. This functionality is selected as described in the chip configuration chapter, and is reflected in the read-only RCR[RMII_MODE] bit. The RCR[RMII_10T] bit determines the speed of operation. The reference clock for RMII is always 50 MHz, but this clock can be divided by 10 within the RCR register to support 10 Mbps operation. The PHY must be configured accordingly.

50.2.2.3 10 Mbps 7-wire interface operation

The FEC supports 7-wire interface used by many 10 Mbps Ethernet transceivers. The RCR[MII_MODE] bit controls this functionality. If this bit is cleared, MII mode is disabled and the 10 Mbps 7-wire mode is enabled.

50.2.3 Address recognition options

The address options supported are:

- Promiscuous
- Broadcast reject
- Individual address (hash or exact match)
- Multicast hash match

Address recognition options are discussed in detail in [Section 50.5.11, Ethernet address recognition](#).

50.2.4 Internal loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in [Section 50.5.16, MII internal and external loopback](#).

p. Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.

50.3 External signal description

[Table 876](#) describes the various FEC signals, as well as indicating which signals work in available modes.

Table 876. FEC signal descriptions⁽¹⁾

Signal name	MII	7-wire	RMII	Description
FEC_COL	X	X	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.
FEC_CRD	X	—	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the FEC_RXDV pin.
FEC_MDC	X	—	—	Output clock provides a timing reference to the PHY for data transfers on the FEC_MDIO signal.
FEC_MDIO	X	—	—	Transfers control information between the external PHY and the media-access controller. Data is synchronous to FEC_MDC. This signal is an input after reset. When the FEC operates in 10Mbps 7-wire interface mode, this signal should be connected to VSS.
FEC_RXCLK	X	X	—	Provides a timing reference for FEC_RXDV, FEC_RXD[3:0], and FEC_RXER.
FEC_RXDV	X	X	X	Asserting the FEC_RXDV input indicates PHY has valid nibbles present on the MII. FEC_RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Assertion of FEC_RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.
FEC_RXD0	X	X	X	This pin contains the Ethernet input data transferred from PHY to the media-access controller when FEC_RXDV is asserted.
FEC_RXD1	X	—	X	This pin contains the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXD[3:2]	X	—	—	These pins contain the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.
FEC_RXER	X	—	X	When asserted with FEC_RXDV, indicates PHY detects an error in the current frame. When FEC_RXDV is not asserted, FEC_RXER has no effect.
FEC_TXCLK	X	X	X	Input clock which provides a timing reference for FEC_TXEN, FEC_TXD[3:0] and FEC_TXER. In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.
FEC_TXD0	X	X	X	The serial output Ethernet data and only valid during the assertion of FEC_TXEN.
FEC_TXD1	X	—	X	This pin contains the serial output Ethernet data and valid only during assertion of FEC_TXEN.
FEC_TXD[3:2]	X	—	—	These pins contain the serial output Ethernet data and valid only during assertion of FEC_TXEN.

Table 876. FEC signal descriptions⁽¹⁾ (continued)

Signal name	MII	7-wire	RMII	Description
FEC_TXEN	X	X	X	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is negated before the first FEC_TXCLK following the final nibble of the frame.
FEC_TXER	X	—	—	When asserted for one or more clock cycles while FEC_TXEN is also asserted, PHY sends one or more illegal symbols. FEC_TXER has no effect at 10 Mbps or when FEC_TXEN is negated.

1. Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.

50.4 Memory map and register definition

The FEC is programmed by a combination of control/status registers (CSRs) and buffer descriptors. The CSRs control operation modes and extract global status information. The descriptors pass data buffers and related buffer information between the hardware and software.

Each FEC implementation requires a 1 KB memory map space, which is divided into two sections of 512 bytes each for:

- Control/status registers
- Event/statistic counters held in the MIB block

[Table 877](#) defines the top-level memory map.

Table 877. FEC memory map

Address offset	Function
000h–1FFh	Control/status registers
200h–3FFh	MIB block counters

[Table 878](#) shows the FEC register map. Any address offset not explicitly mentioned in [Table 878](#) is reserved. Do not modify the content of reserved fields. All accesses to and from the registers must be via 32-bit accesses. There is no support for accesses other than 32-bit. Accessing reserved or unimplemented register spaces in the FEC will not return transfer errors.

The MIB counters (shown in [Table 878](#)) define the locations in the MIB RAM space where hardware-maintained counters reside. The counters are divided into two groups:

- RMON counters include the Ethernet statistics counters defined in RFC 1757
- Truncated frames counter (only frames with lengths up to 2047 bytes are supported)

The transmit and receive RMON counters are independent, which ensures accurate network statistics when operating in full duplex mode.

The included IEEE counters support the mandatory and recommended counter packages defined in Section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The FEC supports IEEE Basic Package objects, but these do not require counters in the MIB block. In addition, some of the recommended package objects supported do not require MIB counters. Counters for transmit and receive full duplex flow control frames are also included.

50.4.1 Interrupt Event Register (EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

These interrupts can be divided into operational interrupts, transceiver/network error interrupts, and internal error interrupts. Interrupts which may occur in normal operation are GRA, TXF, TXB, RXF, RXB, and MII. Interrupts resulting from errors/problems detected in the network or transceiver are HBERR, BABR, BABT, LC, and RL. Interrupts resulting from internal errors are HBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters:

- HBERR - IEEE_T_SQE
- BABR - RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
- BABT - RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
- LATE_COL - IEEE_T_LCOL
- COL_RETRY_LIM - IEEE_T_EXCOL
- XFIFO_UN - IEEE_T_MACERR

Software may choose to mask off these interrupts because these errors are visible to network management via the MIB counters.

Figure 852. Interrupt Event Register (EIR)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 879. EIR field descriptions

Field	Description
HBERR	Heartbeat error. Indicates TCR[HBC] is set and that the COL input was not asserted within the heartbeat window following a transmission.
BABR	Babbling receive error. Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
BABT	Babbling transmit error. Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused by a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
GRA	Graceful stop complete. Indicates the graceful stop is complete. During graceful stop the transmitter is placed into a pause state after completion of the frame currently being transmitted. This bit is set by one of these conditions: – A graceful stop initiated by the setting of the TCR[GTS] bit is now complete. – A graceful stop initiated by the setting of the TCR[TFC_PAUSE] bit is now complete. – A graceful stop initiated by the reception of a valid full duplex flow control pause frame is now complete. See Section 50.5.13, Full duplex flow control.
TXF	Transmit frame interrupt. Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
TXB	Transmit buffer interrupt. Indicates a transmit buffer descriptor has been updated.
RXF	Receive frame interrupt. Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
RXB	Receive buffer interrupt. Indicates a receive buffer descriptor not the last in the frame has been updated.
MII	MII interrupt. Indicates the MII has completed the data transfer requested.
EBERR	Ethernet bus error. Indicates a system bus error occurred when a DMA transaction is underway. When the EBERR bit is set, ECR[ETHER_EN] is cleared, halting frame processing by the FEC. When this occurs, software needs to ensure that the FIFO controller and DMA also soft reset.
LC	Late collision. Indicates a collision occurred beyond the collision window (slot time) in half duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.

Table 879. EIR field descriptions (continued)

Field	Description
RL	Collision retry limit. Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half duplex mode.
UN	Transmit FIFO underrun. Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.

50.4.2 Interrupt Mask Register (EIMR)

The EIMR register controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit.

Each bit in this register corresponds to an interrupt source defined by the EIR register. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every processor clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is set.

Figure 853. Ethernet Interrupt Mask Register (EIMR)

RL	Collision retry limit interrupt mask. 0 The interrupt source is masked. 1 The interrupt source is not masked.
UN	Transmit FIFO underrun interrupt mask. 0 The interrupt source is masked. 1 The interrupt source is not masked.

50.4.3 Receive Descriptor Active Register (RDAR)

RDAR is a command register, written by the user, indicating the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (if ECR[ETHER_EN] is also set). After the FEC polls a receive descriptor whose empty bit is not set, FEC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

The RDAR register is cleared at reset and when ECR[ETHER_EN] is cleared.

Figure 854. Receive Descriptor Active Register (RDAR)

Table 881. RDAR field descriptions

Field	Description
RDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC when no additional empty descriptors remain in the receive ring. Also cleared when ECR[ETHER_EN] is cleared.

50.4.4 Transmit Descriptor Active Register (TDAR)

The TDAR is a command register which the user writes to indicate the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR field is set. This value is independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and processes transmit frames (provided ECR[ETHER_EN] is also set). After the FEC polls a transmit descriptor that is a ready bit not set, FEC clears the TDAR field and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

The TDAR field is cleared when any of the following events occur:

- Chip reset
- When ECR[ETHER_EN] is cleared
- When ECR[RESET] is set

Figure 855. Transmit Descriptor Active Register (TDAR)

Table 882. TDAR field descriptions

Field	Description
TDAR	Set to 1 when this register is written, regardless of the value written. Cleared by the FEC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHER_EN] is cleared.

50.4.5 Ethernet Control Register (ECR)

ECR is a read/write user register, though hardware may alter fields in this register as well. The ECR enables/disables the FEC.

Figure 856. Ethernet Control Register (ECR)

Offset: 024h								Access: User read/write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	ETHER_EN	RESET
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 883. ECR field descriptions

Field	Description
ETHER_EN	When this bit is set, FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware alters the ETHER_EN bit under the following conditions: – ECR[RESET] is set by software, in which case ETHER_EN is cleared. – An error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN is cleared.
RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ECR[ETHER_EN] is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately eight internal bus clock cycles after this bit is set.

50.4.6 MII Management Frame Register (MMFR)

The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to the MMFR causes a

management frame to be sourced unless the MSCR is programmed to 0. If MSCR is cleared while MMFR is written and then MSCR is written with a non-zero value, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

The MMFR does not reset to any predefined value.

Figure 857. MII Management Frame Register (MMFR)

Table 884. MMFR field descriptions

Field	Description
ST	Start of frame delimiter. These bits must be programmed to 0b01 for a valid MII management frame.
OP	Operation code. 00 Write frame operation, but not MII compliant. 01 Write frame operation for a valid MII management frame. 10 Read frame operation for a valid MII management frame. 11 Read frame operation, but not MII compliant.
PA	PHY address. This field specifies one of up to 32 attached PHY devices.
RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

To perform a read or write operation on the MII Management Interface, write the MMFR. To generate a valid read or write management frame, ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated, but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII Management Interface write frame (write to a PHY register), write {01 01 PHYAD REGAD 10 DATA} to the MMFR. Writing this pattern causes the control logic to shift out the data in the MMFR register following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the write management frame operation completes, the MII interrupt is generated. At this time, contents of the MMFR match the original value written.

To generate an MII management interface read frame (read a PHY register), write {01 10 PHYAD REGAD 10 XXXX} to the MMFR (the content of the DATA field is unimportant). Writing this pattern causes the control logic to shift out the data in the MMFR register following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the read management frame operation completes, the MII interrupt is generated. At this time, the contents of the MMFR register match the original value written.

except for the DATA field whose contents are replaced by the value read from the PHY register.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

50.4.7 MII Speed Control Register (MSCR)

The MSCR:

- Provides control of the MII clock (FEC_MDC pin) frequency
- Allows a preamble drop on the MII management frame

Figure 858. MII Speed Control Register (MSCR)

Offset: 044h																				Access: User read/write												
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DIS PRE	MII_SPEED						0
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 885. MSCR field descriptions

Field	Description
DIS_PRE	Setting this bit causes the preamble (32 ones) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
MII_SPEED	Controls the frequency of the MII management interface clock (FEC_MDC) relative to the internal bus clock. A value of 0 in this field turns off the FEC_MDC and leaves it in low voltage state. Any non-zero value results in the FEC_MDC frequency of $1/(MII_SPEED \times 2)$ of the internal bus frequency.

The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be set to 0 to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED changes during operation (change takes effect following a rising or falling edge of FEC_MDC).

If the internal bus clock is 25 MHz, programming this register to 0000_0005h results in an FEC_MDC as stated the equation below.

Equation 37 $25 \text{ MHz} \times \frac{1}{5 \times 2} = 2.5 \text{ MHz}$

[Table 886](#) shows optimum values for MII_SPEED as a function of internal bus clock frequency.

Table 886. Programming examples for MSCR

Internal FEC clock frequency	MSCR[MII_SPEED]	FEC_MDC frequency
25 MHz	5h	2.50 MHz
33 MHz	7h	2.36 MHz
40 MHz	8h	2.50 MHz
50 MHz	Ah	2.50 MHz
66 MHz	Eh	2.36 MHz
80 MHz	10h	2.50 MHz
83 MHz	10h	2.59 MHz

50.4.8 MIB Control Register (MIBC)

The MIBC is a read/write register controlling and observing the state of the MIB block. User software accesses this register if there is a need to disable the MIB block operation. For example, to clear all MIB counters in RAM:

1. Disable the MIB block
2. Clear all the MIB RAM locations
3. Enable the MIB block

The MIB_DIS bit is reset to 1. See the memory map for the locations of the MIB counters.

Figure 859. MIB Control Register (MIBC)

Table 887. MIBC field descriptions

Field	Description
MIB_DIS	If MIB_DIS = 1, the MIB logic halts and not update any MIB counters.
MIB_IDLE	If MIB_IDLE = 1, the MIB block is not currently updating any MIB counters.

50.4.9 Receive Control Register (RCR)

RCR controls the operational mode of the receive block and must be written only when ECR[ETHER_EN] is cleared (initialization time).

Figure 860. Receive Control Register (RCR)

Table 888. RCR field descriptions

Field	Description
MAX_FL	Maximum frame length. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
RMII_ECHO	RMII Echo. Enables RMII echo mode. RMII 2-bit receive data is processed through the RMII receive logic to the FEC and also routes through the RMII's transmit logic to become RMII 2-bit transmit data out. 0 Normal operation. 1 RMII echo mode enabled. <i>Note: When RMII_ECHO is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_LOOP = 0 and LOOP = 0.</i>
RMII_LOOP	RMII loopback. Enables RMII loopback mode. Causes the MII transmit outputs from the Ethernet controller to loop back to the Ethernet controllers's MII receive inputs through the RMII transmit/receive logic. 0 Normal operation. 1 RMII loopback mode enabled. <i>Note: When RMII_LOOP is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_ECHO = 0, LOOP = 0, and TCRn[FDEN] = 1.</i>

Table 888. RCR field descriptions (continued)

Field	Description
RMII_10T	RMII 10-Base T. Enables 10Mbps mode of the RMII. Determines the clock frequency of the clock source to the FEC logic to support 10/100Mbps operations. 0 100 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is sent to the RMII, while a divided-by-2 version (25 MHz) is sent to the FEC. 1 10 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is divided by 10 (5 MHz) and sent to the RMII, while a divided-by-20 version (2.5 MHz) is sent to the FEC.
RMII_MODE	RMII Mode. Indicates if the FEC is in RMII or MII/7-wire mode. See the chip configuration chapter for more details. 0 FEC is in true MII mode. 1 FEC is in RMII mode. <i>Note: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.</i>
FCE	Flow control enable. If asserted, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
BC_REJ	Broadcast frame reject. If asserted, frames with DA (destination address) equal to FFFF_FFFF_FFFF are rejected unless the PROM bit is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the M (MISS) is set in the receive buffer descriptor.
PROM	Promiscuous mode. All frames are accepted regardless of address matching.
MII_MODE	Media independent interface mode. Selects the external interface mode for transmit and receive blocks. 0 7-wire mode (used only for serial 10 Mbps) 1 MII or RMII mode as indicated by the RMII_MODE bit <i>Note: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.</i>
DRT	Disable receive on transmit. 0 Receive path operates independently of transmit (use for full duplex or to monitor transmit activity in half duplex mode). 1 Disable reception of frames while transmitting (normally used for half duplex mode).
LOOP	Internal loopback. If set, transmitted frames are looped back internal to the device and transmit output signals are not asserted. The internal bus clock substitutes for the FEC_TXCLK when LOOP is asserted. DRT must be set to 0 when setting LOOP.

50.4.10 Transmit Control Register (TCR)

The TCR configures the transmit block.

Figure 861. Transmit Control Register (TCR)

Offset: 0C4h

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 889. TCR field descriptions

Field	Description
RFC_PAUSE	Receive frame control pause. This read-only status bit is asserted when a full duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete.
TFC_PAUSE	Transmit frame control pause. Transmits a PAUSE frame when asserted. When this bit is set, the MAC stops transmission of data frames after the current transmission is complete. At this time, GRA interrupt in the EIR is asserted. With transmission of data frames stopped, MAC transmits a MAC Control PAUSE frame. Next, the MAC clears the TFC_PAUSE bit and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC Control PAUSE frame.
FDEN	Full duplex enable. If set, frames transmit independent of carrier sense and collision inputs. This field must be modified only when ECR[ETHER_EN] = 0.
HBC	Heartbeat control. If set, the heartbeat check performs following end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This field must be modified only when ECR[ETHER_EN] = 0.
GTS	Graceful transmit stop. When this bit is set, MAC stops transmission after any frame currently transmitted is complete and GRA interrupt in the EIR is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this situation, program ECR[ETHER_EN] = 0 following the GRA interrupt.

50.4.11 Physical Address Lower Register (PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the 6-byte source address field when transmitting PAUSE frames.

This register is not reset and you must initialize it.

Figure 862. Physical Address Lower Register (PALR)

Table 890. PALR field descriptions

Field	Description
PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

50.4.12 Physical Address Upper Register (PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte Source Address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (8808h) for transmission of PAUSE frames. The upper 16 bits of this register are not reset and you must initialize it.

Figure 863. Physical Address Upper Register (PAUR)

Table 891. PAUR field descriptions

Field	Description
PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
TYPE	Type field in PAUSE frames. These 16 read-only bits are a constant value of 8808h.

50.4.13 Opcode/Pause Duration Register (OPD)

The OPD contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0001h. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field.

The lower 16 bits of this register are not reset and you must initialize them.

Figure 864. Opcode/Pause Duration Register (OPD)**Table 892. OPD field descriptions**

Field	Description
OPCODE	Opcode field used in PAUSE frames. These read-only bits are a constant, 0001h.
PAUSE_DUR	Pause Duration field used in PAUSE frames.

50.4.14 Descriptor Individual Upper Address Register (IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Figure 865. Descriptor Individual Upper Address Register (IAUR)**Table 893. IAUR field descriptions**

Field	Description
IADDR1	The upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

50.4.15 Descriptor Individual Lower Address Register (IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Figure 866. Descriptor Individual Lower Address Register (IALR)

Table 894. IALR field descriptions

Field	Description
IADDR2	The lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0.

50.4.16 Descriptor Group Upper Address Register (GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address.

This register is not reset and you must initialize it.

Figure 867. Descriptor Group Upper Address Register (GAUR)

Table 895. GAUR field descriptions

Field	Description
GADDR1	The GADDR1 register contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

50.4.17 Descriptor Group Lower Address Register (GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address.

This register is not reset and you must initialize it.

Figure 868. Descriptor Group Lower Address Register (GALR)**Table 896. GALR field descriptions**

Field	Description
GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

50.4.18 Transmit FIFO Watermark Register (TFWR)

The TFWR controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement (worst case bus access latency by the transmit data DMA channel).

Figure 869. Transmit FIFO Watermark Register (TFWR)**Table 897. TFWR field descriptions**

Field	Description
TFWR	Number of bytes written to transmit FIFO before transmission of a frame begins 00 64 bytes written 01 64 bytes written 10 128 bytes written 11 192 bytes written

50.4.19 FIFO Receive Bound Register (FRBR)

FRBR indicates the upper address bound of the FIFO RAM. Drivers can use this value, along with the FRSR, to appropriately divide the available FIFO RAM between the transmit and receive data paths.

Figure 870. FIFO Receive Bound Register (FRBR)

Offset: 14Ch

Access: User read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 898. FRBR field descriptions

Field	Description
R_BOUND	Highest valid FIFO RAM address.

50.4.20 FIFO Receive Start Register (FRSR)

FRSR indicates the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

Hardware initializes the FRSR at reset. FRSR only needs to be written to change the default value.

Figure 871. FIFO Receive Start Register (FRSR)

Offset: 150h

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Table 899. FRSR field descriptions

Field	Description
R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs. For proper operation, ensure that R_FSTART is set to 48h or greater.

50.4.21 Receive Descriptor Ring Start Register (ERDSR)

ERDSR points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Figure 872. Receive Descriptor Ring Start Register (ERDSR)**Table 900. ERDSR field descriptions**

Field	Description
R_DES_START	Pointer to start of receive buffer descriptor queue.

50.4.22 Transmit Buffer Descriptor Ring Start Register (ETSDR)

ETSDR provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Figure 873. Transmit Buffer Descriptor Ring Start Register (ETSDR)**Table 901. ETSDR field descriptions**

Field	Description
X_DES_START	Pointer to start of transmit buffer descriptor queue.

50.4.23 Receive Buffer Size Register (EMRBR)

The EMRBR dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX_FL] or larger. To properly align the buffer, EMRBR must be evenly divisible by 16. To ensure this, bits 3–0 are forced low.

To minimize bus utilization (descriptor fetches), it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR register is undefined at reset and must be initialized by the user.

Figure 874. Receive Buffer Size Register (EMRBR)

Table 902. EMRBR field descriptions

Field	Description
R_BUF_SIZE	Maximum size of receive buffer size in bytes. To minimize bus utilization (descriptor fetches), set this field to 256 bytes (10h) or larger. 10h 256 + 15 bytes (minimum size recommended) 11h 272 + 15 bytes ... 7Fh 2032 + 15 bytes. The FEC writes up to 2047 bytes in the receive buffer. If data larger than 2047 is received, the FEC truncates it and shows 7FFh in the receive descriptor

50.5 Functional description

This section describes the operation of the FEC, beginning with the description of two different types of MII frames, the buffer descriptors, the hardware and software initialization sequence, then the software (Ethernet driver) interface for transmitting and receiving frames.

Following the software initialization and operation sections are sections providing a detailed description of the functions of the FEC.

50.5.1 MII data frame

Ethernet/802.3 data frames transmitted across the MII have the format specified in [Figure 930](#) and [Table 958](#).

Figure 930. MII data frame format

<inter-frame> <preamble> <sfd> <data> <efd>

Table 958. MII data frame components

Component	Description
<inter-frame>	Inter-frame period. This is an unspecified amount of time during which no data activity occurs on the MII. The de-assertion of RX_DV and TX_EN indicate the absence of data activity.
<preamble>	Preamble that begins a frame. It has the following value: 10101010 10101010 10101010 10101010 10101010 10101010 10101010 The leftmost 1 represents the LSB of the byte.
<sfd>	Start of a frame. It has the value 10101011.

Table 958. MII data frame components (continued)

Component	Description
<data>	Data portion of the frame. It consists of N octets which corresponds to 2N nibbles being transmitted. The order of each nibble is defined in Figure 931 .
<efd>	End-of-frame delimiter. For TXD data, it is indicated by the de-assertion of the TX_EN signal. For RXD data, it is indicated by the de-assertion of the RX_DV signal.

Figure 931. MII nibble/octet to octet/nibble mapping

50.5.2 MII management frame structure

A transceiver management frame being transmitted on the MII management interface uses the MDIO and MDC pins. A transaction or frame on this serial interface has the format specified in [Figure 932](#) and [Table 959](#).

Figure 932. MII management frame format

<preamble> <st> <op> <phyad> <regad> <ta> <data> <idle>

Table 959. MII management frame components

Component	Description
<preamble>	Optional preamble, consisting of a sequence of 32 continuous logic 1's.
<st>	Start of frame, consisting of a 01 pattern.
<op>	Operation code. 01 Write operation 10 Read instruction
<phyad>	Five-bit field that allows up to 32 PHYs to be addressed. The first address bit transmitted is the MSB of the address.

Table 959. MII management frame components (continued)

Component	Description
<regad>	Five-bit field that allows for 32 registers to be addressed within each PHY. The first register bit transmitted is the MSB of the address.
<ta>	Two-bit field that provides spacing between the register address field and the data field to avoid contention on the MDIO signal during a read operation.
<data>	16-bit data field. Bit 15 is the first data bit transmitted and received.
<idle>	Idle condition (MDIO is in the high-impedance state).

The MII management register set located in the PHY may consist of a basic register set and an extended register set as defined in [Table 960](#).

Table 960. MII management register set

Register address	Register name	Register set
0	Control	Basic
1	Status	
2–3	PHY identifier	Extended
4	Auto-negotiation advertisement	
5	AN link partner ability	
6	AN expansion	
7	AN next page transmit	
8–15	Reserved	
16–31	Vendor-specific	

50.5.3 Buffer descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields.

50.5.3.1 Driver/DMA operation with buffer descriptors

The data for the FEC frames resides in one or more memory buffers external to the FEC. Associated with each buffer is a buffer descriptor (BD), which contains a starting address (32-bit aligned pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read by the FEC DMA engine.

Software produces buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit produces the buffer. Software writing to TDAR or RDAR tells the FEC that a buffer is placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and consumes the buffers after they have been produced. After the data DMA is complete and the DMA engine writes the buffer descriptor status bits, hardware clears RxBD[E] or TxBD[R] to signal the buffer has been consumed. Software may poll the BDs to detect when the buffers are consumed.

or may rely on the buffer/frame interrupts. The driver may process these buffers, and they can return to the free list.

The ECR[ETHER_EN] bit operates as a reset to the BD/DMA logic. When ECR[ETHER_EN] is cleared, the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before ECR[ETHER_EN] is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The wrap (W) bit defines the last buffer descriptor in each ring. When W is set, the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively. Buffer descriptor rings must start on a 32-bit boundary; however, it is recommended they be 128-bit aligned.

50.5.3.1.1 Driver/DMA operation with transmit BDs

Typically, a transmit frame is divided between multiple buffers. An example is to have an application payload in one buffer, TCP header in a second buffer, IP header in a third buffer, and Ethernet/IEEE 802.3 header in a fourth buffer. The Ethernet MAC does not prepend the Ethernet header (destination address, source address, length/type field(s)), so the driver must provide this in one of the transmit buffers. The Ethernet MAC can append the Ethernet CRC to the frame. TxBD[TC], which must be set by the driver, determines whether the MAC or driver appends the CRC.

The driver (TxBD software producer) should set up Tx BDs so a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, the BDs should be initialized with pointer, length, and control (W, L, TC, ABC) and then the TxBD[R] bit should be set in reverse order (third, second, then first BD) to ensure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the second was made available, potentially causing a transmit FIFO underrun.

In the FEC, the driver notifies the DMA that new transmit frame(s) are available by writing to TDAR. When this register is written to (data value is not significant), the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers until a transmit BD is encountered with the R bit cleared. At this point, the FEC polls this BD one more time. If the R bit is cleared the second time, RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

50.5.3.1.2 Driver/DMA operation with receive BDs

Unlike transmit, the length of the receive frame is unknown by the driver ahead of time. Therefore, the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) should set up some number of empty buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L is set), and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end-of-frame buffers, the receive BD is written with L set and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame should be discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not only the length of the last buffer.

For simplicity, the driver may assign a large enough default receive buffer length to contain an entire frame, keeping in mind that a malfunction on the network or out-of-spec implementation could result in giant frames. Frames of 2K (2048) bytes or larger are truncated by the FEC at 2047 bytes so software never sees a receive frame larger than 2047 bytes.

Similar to transmit, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received, the FEC fills receive buffers and updates the associated BDs, then reads the next BD in the receive descriptor ring. If the FEC reads a receive BD and finds the E bit cleared, it polls this BD once more. If RxBD[E] is clear a second time, FEC stops reading receive BDs until the driver writes to RDAR.

50.5.3.2 Ethernet Receive Buffer Descriptor (RxBD)

In the RxBD, the user initializes the E and W bits in the first longword and the pointer in the second longword. When the buffer has been DMA'd, the Ethernet controller modifies the E, L, M, BC, MC, LG, NO, CR, OV, and TR bits and writes the length of the used portion of the buffer in the first longword. The M, BC, MC, LG, NO, CR, OV, and TR bits in the first longword of the buffer descriptor are only modified by the Ethernet controller when the L bit is set.

Figure 933. Receive Buffer Descriptor (RxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 2	Data Length															
Offset + 4	Rx Data Buffer Pointer - A[31:16]															
Offset + 6	Rx Data Buffer Pointer - A[15:0]															

Table 961. Receive Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	E	Empty. Written by the FEC (=0) and user (=1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.

Table 961. Receive Buffer Descriptor field descriptions (continued)

Word	Field	Description
Offset + 0	W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ERDSR.
Offset + 0	RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by the FEC. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 0	M	Miss. Written by the FEC. This bit is set by the FEC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.
Offset + 0	BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 0	MC	Set if the DA is multicast and not BC.
Offset + 0	LG	Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
Offset + 0	NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set, the CR bit is not set.
Offset + 0	CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.
Offset + 0	OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and are zero. This bit is valid only if the L-bit is set.
Offset + 0	TR	Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set, the frame must be discarded and the other error bits must be ignored as they may be incorrect.
Offset + 2	Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L equals 0 (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the FEC once as the BD is closed.
Offset + 4	A[31:16]	RX data buffer pointer, bits [31:16] ⁽¹⁾
Offset + 6	A[15:0]	RX data buffer pointer, bits [15:0]

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the FEC. The Ethernet controller never modifies this value.

Note: When the software driver sets an E bit in one or more receive descriptors, the driver should follow with a write to RDAR.

50.5.3.3 Ethernet Transmit Buffer Descriptor (TxBD)

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. The Ethernet controller confirms transmission by clearing the ready bit (TxBD[R]) when DMA of the buffer is complete. In the TxBD, the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword and the buffer pointer in the second longword.

The FEC clears the R bit when the buffer is transferred. Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block. See the memory map for more details.

Figure 934. Transmit Buffer Descriptor (TxBD)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	R	TO1	W	TO2	L	TC	ABC	—	—	—	—	—	—	—	—	—
Offset + 2	Data Length															
Offset + 4	Tx Data Buffer Pointer - A[31:16]															
Offset + 6	Tx Data Buffer Pointer - A[15:0]															

Table 962. Transmit Buffer Descriptor field descriptions

Word	Field	Description
Offset + 0	R	Ready. Written by the FEC and you. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this bit is set.
Offset + 0	TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware nor does its value affect hardware.
Offset + 0	L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 0	TC	Transmit CRC. Written by user (only valid if L is set). 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte
Offset + 0	ABC	Append bad CRC. Written by user (only valid if L is set). 0 No effect 1 Transmit the CRC sequence inverted after the last data byte (regardless of TC value)

Table 962. Transmit Buffer Descriptor field descriptions (continued)

Word	Field	Description
Offset + 2	Data Length	Data length, written by user. Data length is the number of octets the FEC should transmit from this BD's data buffer. It is never modified by the FEC.
Offset + 4	A[31:16]	Tx data buffer pointer, bits [31:16] ⁽¹⁾
Offset + 6	A[15:0]	Tx data buffer pointer, bits [15:0]

1. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 4. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

Note: After the software driver has set up the buffers for a frame, it should set up the corresponding BDs. The last step in setting up the BDs for a transmit frame is setting the *R* bit in the first BD for the frame. The driver must follow that with a write to TDAR that triggers the FEC to poll the next BD in the ring.

50.5.4 Initialization sequence

This section describes which registers are reset due to hardware reset, which registers are reset by the FEC RISC, and what locations you must initialize prior to enabling the FEC.

50.5.4.1 Hardware Controlled Initialization

In the FEC, hardware resets registers and control logic that generate interrupts. A hardware reset negates output signals and resets general configuration bits.

Other registers reset when the ECR[ETHER_EN] bit is cleared (which is accomplished by a hard reset or software to halt operation). By clearing ECR[ETHER_EN], configuration control registers such as the TCR and RCR are not reset, but the entire data path is reset.

Table 963. ECR[ETHER_EN] De-Assertion Effect on FEC

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
RDAR	Cleared
TDAR	Cleared
Descriptor Controller block	Halt operation

50.5.5 User initialization (Prior to Setting ECR[ETHER_EN])

You need to initialize portions the FEC prior to setting the ECR[ETHER_EN] bit. The exact values depend on the particular application. The sequence is not important.

The following registers require initialization:

- EIMR
- EIR (clear by writing FFFF_FFFFh)
- TFWR (optional)
- IALR / IAUR
- GAUR / GALR
- PALR / PAUR (only needed for full duplex flow control)
- OPD (only needed for full duplex flow control)
- RCR
- TCR
- MSCR (optional)
- MIB_RAM (clear)
- FRSR (optional)
- EMRBR
- ERDSR
- ETDSR
- Transmit Descriptor ring (empty)
- Receive Descriptor ring (empty)

50.5.6 Microcontroller initialization

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, hardware is ready for operation.

The sequence is as follows:

1. Initialize the backoff random number seed.
2. Activate receiver.
3. Activate transmitter.
4. Clear transmit FIFO.
5. Clear receive FIFO.
6. Initialize the transmit ring pointer.
7. Initialize the receive ring pointer.
8. Initialize FIFO count registers.

50.5.7 User initialization (after setting ECR[ETHER_EN])

After setting ECR[ETHER_EN], you can set up the buffer/frame descriptors and write to TDAR and RDAR. See [Section 50.5.3, Buffer descriptors](#), for more details.

50.5.8 Network interface options

The FEC supports an MII and reduced MII interface for 10/100 Mbps Ethernet, as well as a 7-wire serial interface for 10 Mbps Ethernet. The RCR[MII_MODE] and RCR[RMII_MODE] bits select the interface mode. In MII mode (RCR[MII_MODE] = 1 and RCR[RMII_MODE] = 0), there are 18 signals defined by the IEEE 802.3 standard and supported by the EMAC. [Table 964](#) shows these signals.

Table 964. MII mode

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[3:0]
Transmit Error	FEC_TXER
Collision	FEC_COL
Carrier Sense	FEC_CRS
Receive Clock	FEC_RXCLK
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[3:0]
Receive Error	FEC_RXER
Management Data Clock	FEC_MDC
Management Data Input/Output	FEC_MDIO

In RMII mode ($\text{RCR}[\text{MII_MODE}] = 1$ and $\text{RCR}[\text{RMII_MODE}] = 1$), the EMAC supports 8 external signals. These signals are shown in [Table 965](#) below.

Table 965. RMII mode configuration

Signal description	EMAC pin
Reference Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN
Transmit Data	FEC_TXD[1:0]
Receive Data Valid	FEC_RXDV
Receive Data	FEC_RXD[1:0]
Receive Error	FEC_RXER

The 7-wire serial mode interface ($\text{RCR}[\text{MII_MODE}] = 1$ and $\text{RCR}[\text{RMII_MODE}] = 0$ or 1) is generally referred to as AMD mode. [Table 966](#) shows the 7-wire mode connections to the external transceiver.

Table 966. 7-Wire mode configuration

Signal description	EMAC pin
Transmit Clock	FEC_TXCLK
Transmit Enable	FEC_TXEN

50.5.9 FEC frame transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After ECR[ETHER_EN] is set and data appears in the transmit FIFO, the Ethernet MAC can transmit onto the network. The Ethernet controller transmits bytes least significant bit (lsb) first.

When the transmit FIFO fills to the watermark (defined by TFWR), MAC transmit logic asserts FEC_TXEN and starts transmitting the

(PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller defers the transmission if the network is busy (FEC_CRSS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense stays inactive for 60 bit times. If so, transmission begins after waiting an additional 36 bit times (96 bit times after carrier sense originally became inactive). See [Section 50.5.19.1, Transmission errors](#), for more details.

If a collision occurs during transmission of the frame (half duplex mode), the Ethernet controller follows the specified backoff procedures and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data is transmitted, FCS (frame check sequence) or 32-bit cyclic redundancy check (CRC) bytes are appended if the TC bit is set in the transmit frame control word. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Transmit logic automatically pads short frames (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set).

Settings in the EIMR determine interrupts generated to the buffer (TXB) and frame (TXF).

The transmit error interrupts are HBERR, BABT, LC, RL, and UN. If the transmit frame length exceeds MAX_FL bytes, BABT interrupt is asserted. However, the entire frame is transmitted (no truncation).

To pause transmission, set TCR[GTS] (graceful transmit stop). The FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame finishes or terminates with a collision. After the transmitter has stopped, the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

50.5.9.1 Duplicate frame transmission

The FEC fetches transmit buffer descriptors (TxBDs) and the corresponding transmit data continuously until the transmit FIFO is full. It does not determine whether the TxBD to be

fetches is already being processed internally (as a result of a wrap). As the FEC nears the end of the transmission of one frame, it begins to DMA the data for the next frame. To remain one BD ahead of the DMA, it also fetches the TxBD for the next frame. It is possible that the FEC fetches from memory a BD that has already been processed but not yet written back (it is read a second time with the R bit remains set). In this case, the data is fetched and transmitted again.

Using at least three TxBDs fixes this problem for large frames, but not for small frames. To ensure correct operation for large or small frames, one of the following must be true:

- The FEC software driver ensures that there is always at least one TxBD with the ready bit cleared.
- Every frame uses more than one TxBD and every TxBD but the last is written back immediately after the data is fetched.
- The FEC software driver ensures a minimum frame size, n . The minimum number of TxBDs is then $(\text{Tx FIFO Size} \div (n + 4))$ rounded up to the nearest integer (though the result cannot be less than three). The default Tx FIFO size is 192 bytes; this size is programmable.

50.5.10 FEC frame reception

The FEC receiver works with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking. The Ethernet controller receives serial data lsb first.

When the driver enables the FEC receiver by setting ECR[ETHER_EN], it immediately starts processing receive frames. When FEC_RXDV is asserted, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the receiver processes the frame. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit times of RX_D0 following assertion of FEC_RXDV are ignored. Following the first 16 bit times, the data sequence is checked for alternating 1/0s. If a 11 or 00 data sequence is detected during bit times 17 to 21, the remainder of the frame is ignored. After bit time 21, the data sequence is monitored for a valid SFD (11). If a 00 is detected, the frame is rejected. When a 11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes may occur, but if a 00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame are received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data is received and if address recognition has not rejected the frame, the receive FIFO signals the frame is accepted and may be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Therefore, no collision fragments are presented to you except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV, and TR status bits, and the frame length. See [Section 50.5.19.2, Reception errors](#), for more details.

Receive buffer (RXB) and frame interrupts (RFINT) may be generated if enabled by the EIMR register. A receive error interrupt is a babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR

interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See [Section 50.5.3.2, Ethernet Receive Buffer Descriptor \(RxBD\)](#), for more details.

When the receive frame is complete, the FEC sets the L-bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E-bit. The Ethernet controller next generates a maskable interrupt (RFINT bit in EIR, maskable by RFIEN bit in EIMR), indicating that a frame is received and is in memory. The Ethernet controller then waits for a new frame.

50.5.11 Ethernet address recognition

The FEC filters the received frames based on destination address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the destination address field. A flowchart for address recognition on received frames appears in the figures below.

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in [Figure 935](#) illustrates the address recognition decisions made by the receive block, while [Figure 936](#) illustrates the decisions made by the microcontroller.

If the DA is a broadcast address and broadcast reject (RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in [Figure 935](#). Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in [Figure 936](#).

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame.

If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines the received frame is a valid PAUSE frame, the frame is rejected. The receiver detects a PAUSE frame with the DA field set to the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that you program in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR. In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on PAUSE frame detection, shown in [Figure 935](#).

If neither a hash match (group or individual) nor an exact match (group or individual) occur, and if promiscuous mode is enabled (RCR[PROM] set), the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.

Figure 935. Ethernet address recognition—receive block decisions

Figure 936. Ethernet address recognition—microcode decisions**Notes:**

FCE - field in RCR register (flow control enable)

I/G - Individual/Group bit in destination address (lsb in first byte received in MAC frame)

50.5.12 Hash algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits stored in GAUR, GALR (group address hash match), or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The msb of the CRC result selects GAUR (msb = 1) or GALR (msb = 0). The five least significant bits of the hash result select the bit within the selected register. If the CRC generator selects a bit set in the hash table, the frame is accepted; otherwise, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

Equation 38
$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

[Table 967](#) contains example destination addresses and corresponding hash values.

Table 967. Destination address to 6-bit hash

50.5.13 Full duplex flow control

Full-duplex flow control allows you to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, MAC data frame transmission stops for a given pause duration.

To enable PAUSE frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] set) with flow control (RCR[FCE] set). The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in [Table 968](#). In addition, the receive status associated with the frame should indicate that the frame is valid.

Table 968. PAUSE frame field specification

48-bit destination address	0180_C200_0001h or Physical Address
48-bit source address	Any
16-bit type	8808h
16-bit opcode	0001h
16-bit PAUSE duration	0000h – FFFFh

The receiver and microcontroller modules perform PAUSE frame detection. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is set by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. The pause timer uses the transmit backoff timer hardware for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments once every slot time, until OPD[PAUSE_DUR] slot times have expired. On OPD[PAUSE_DUR] expiration, TCR[GTS] is cleared allowing MAC data frame transmission to resume. The receive flow control pause status bit (TCR[RFC_PAUSE]) is set while the transmitter pauses due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and you must set flow control pause (TCR[TFC_PAUSE]). After TCR[TFC_PAUSE] is set, the transmitter sets TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts and the pause frame is transmitted. TCR[TFC_PAUSE,GTS] are then cleared internally.

You must specify the desired pause duration in the OPD register.

When the transmitter pauses due to receiver/microcontroller pause frame detection, TCR[TFC_PAUSE] may remain set and cause the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

50.5.14 Inter-Packet Gap (IPG) time

The minimum inter-packet gap time for back-to-back transmission is 96 bit times. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96 bit time IPG counter. Frame transmission may begin 96 bit times after carrier sense is negated if it stays negated for at least 60 bit times. If carrier sense asserts during the last 36 bit times, it is ignored and a collision occurs.

The receiver accepts back-to-back frames with a minimum spacing of at least 28 bit times. If an inter-packet gap between receive frames is less than 28 bit times, the receiver may discard the following frame.

50.5.15 Collision managing

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit times, transmitting a JAM pattern consisting of 32 ones. If the collision occurs during the

sequence, a JAM pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit times (one slot time), the retry process is initiated. The transmitter waits a random number of slot times. If a collision occurs after 512 bit times, then no retransmission is performed and the end of frame buffer is closed with a Late Collision (LC) error indication.

50.5.16 MII internal and external loopback

Internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Internal and external loopback are configured using combinations of the RCR[LOOP, DRT] and TCR[FDEN] bits.

Set FDEN for internal and external loopback.

For internal loopback, set RCR[LOOP] and clear RCR[DRT]. FEC_TXEN and FEC_TXER do not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the transmit and receive blocks use the internal bus clock instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underruns and receive FIFO overflows.

For external loopback, clear RCR[LOOP] and RCR[DRT], and configure the external transceiver for loopback.

50.5.17 RMII loopback

The FEC also supports RMII loopback. In this mode, transmit data is sent to the RMII receive logic and out the FEC_TXD[1:0] pins. To enable RMII loopback mode, set RCR[RMII_MODE, RMII_LOOP] and TCR[FDEN] and clear RCR[RMII_ECHO, LOOP].

Figure 937. RMII loopback mode

50.5.18 RMII echo

The Ethernet controller also supports RMII echo mode, which transmits data on FEC_TXD[1:0] as it is received on FEC_RXD[1:0]. To enable RMII echo mode, set RCR[RMII_MODE, RMII_ECHO] bits and clear RCR[RMII_LOOP, LOOP].

Figure 938. RMII echo mode

50.5.19 Ethernet error-managing procedure

The Ethernet controller reports frame reception and transmission error conditions using the MIB block counters, the FEC RxBDs, and the EIR register.

50.5.19.1 Transmission errors

50.5.19.1.1 Transmitter underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error and stops transmitting. All remaining buffers for that frame are then flushed and closed, and EIR[UN] is set. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame. The UN interrupt is asserted if enabled in the EIMR register.

50.5.19.1.2 Retransmission attempts limit expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[RL] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The RL interrupt is asserted if enabled in the EIMR register.

50.5.19.1.3 Late collision

When a collision occurs after the slot time (512 bits starting at the Preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[LC] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The LC interrupt is asserted if enabled in the EIMR register.

50.5.19.1.4 Heartbeat

Some transceivers have a self-test feature called heartbeat or signal quality error. To signify a good self-test, the transceiver indicates a collision to the FEC within four microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver continues to function properly. This is the heartbeat condition.

If TCR[HBC] is set and the heartbeat condition is not detected by the **FEC** after a frame transmission, a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets EIR[HB], and generates the HBERR interrupt if it is enabled.

50.5.19.2 Reception errors

50.5.19.2.1 Overrun error

If the receive block has data to put into the receive FIFO and the receive FIFO is full, FEC sets RxB[OV]. All subsequent data in the frame is discarded and subsequent frames may also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. The driver must discard this frame.

50.5.19.2.2 Non-octet error (dribbling bits)

The Ethernet controller manages up to seven dribbling bits when the receive frame terminates past a non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, the frame non-octet aligned (NO) error is reported in the RxB. If there is no CRC error, no error is reported.

50.5.19.2.3 CRC error

When a CRC error occurs with no dribble bits, FEC closes the buffer and sets RxB[CR]. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

50.5.19.2.4 Frame length violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and RxB[LG] is set. The frame is not truncated unless the frame length exceeds 2047 bytes.

50.5.19.2.5 Truncation

When the receive frame length exceeds 2047 bytes, frame is truncated and RxB[TR] is set.

51 FlexRay Communication Controller (FlexRay)

51.1 Introduction

51.1.1 Reference

The following documents are referenced in this chapter. They may be consulted for further information on the FlexRay Communication Controller's operation.

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A^(q)
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0

51.1.2 Glossary

[Table 969](#) provides a list of terms used in this chapter.

Table 969. List of terms

Term	Definition
BCU	Buffer Control Unit. Handles message buffer access.
BMIF	Bus Master Interface. Provides master access to FlexRay memory area.
CC	Communication Controller
CDC	Clock Domain Crosser
CHI	Controller Host Interface
Cycle length in μT	The actual length of a cycle in μT for the ideal controller (+/- 0 ppm)
EBI	External Bus Interface
FlexRay memory area	Memory area for storing the physical message buffer payload data, frame header, frame and slot status, and synchronization frame-related tables.
System memory	Memory that contains the FlexRay memory area.
System bus	Bus that connects the controller and system memory
FSS	Frame Start Sequence
HIF	Host Interface. Provides host access to controller.
Host	The FlexRay CC host MCU
LUT	Look Up Table. Stores message buffer header index value.
LRAM	Look Up Table RAM. Module internal memory for storing message buffer configuration data and data field offsets for individual message buffers and receive shadow buffers.
MB	Message Buffer
MBIDX	Message Buffer Index. Position of a header field entry within the header area. If the header area is accessed as an array, this is the same as the array index of the entry.

q. The FlexRay Specifications have been developed for automotive applications. The FlexRay Specifications have been neither developed nor tested for non-automotive applications.

Table 969. List of terms (continued)

Term	Definition
MNum	Message Buffer Number. Position of message buffer configuration registers within the register map. For example, Message Buffer Number 5 corresponds to the MBCCS5 register.
MCU	Microcontroller Unit
μ T	Microtick
MT	Macrotick
MTS	Media Access Test Symbol
NIT	Network Idle Time
PE	Protocol Engine
POC	Protocol Operation Control. Each state of the POC is denoted by <i>POC:state</i>
Rx	Reception
SEQ	Sequencer Engine
SEDED	Single-bit error correction, double-bit error detection
TCU	Time Control Unit
Tx	Transmission
sync frame	null frame or message frame with <i>Sync Frame Indicator</i> set to 1
startup frame	null frame or message frame with both <i>Sync Frame Indicator</i> and <i>Startup Frame Indicator</i> set to 1
normal frame	null frame or message frame with both <i>Sync Frame Indicator</i> and <i>Startup Frame Indicator</i> set to 0
null frame	frame with <i>Null Frame Indicator</i> set to 0
message frame	frame with <i>Null Frame Indicator</i> set to 1

51.1.3 Color coding

Throughout this chapter, some items are displayed in an italicized, colored font.

FlexRay protocol parameters, constants, and variables are highlighted with *blue italics*. An example is the parameter *gdActionPointOffset*.

FlexRay protocol states are highlighted in *green italics*. An example is the state *POC:normal active*.

51.1.4 Overview

The communication controller (CC) is a FlexRay communication controller that implements the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

The CC has three main components:

- Controller host interface (CHI)
- Protocol engine (PE)
- Clock domain crossing unit (CDC)

A block diagram of the CC with its surrounding modules is given in [Figure 939](#).

Figure 939. FlexRay block diagram

The protocol engine has two transmitter units, TxA and TxB, and two receiver units, RxA and RxB, for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the protocol engine (PE) is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, as well as the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the controller host interface (CHI) clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the [System Memory Base Address Register \(FR_SYMBADR\)](#). All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note: The CC does not provide a memory protection scheme for the FlexRay memory area.

51.1.5 Features

The CC provides the following features:

- FlexRay Communications System Protocol Specification, Version 2.1 Rev A-compliant protocol implementation
- FlexRay Communications System Electrical Physical Layer Specification, Version 3.0-compliant bus driver interface
- Single channel support
 - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B.
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 128 configurable message buffers with
 - Individual frame ID filtering
 - Individual channel ID filtering
 - Individual cycle counter filtering
- Message buffer header, status, and payload data stored in dedicated FlexRay memory area
 - Allows for flexible and efficient message buffer implementation
 - Ensures consistent data access by means of a buffer-locking scheme
 - Application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0–254 bytes
- Two independent message buffer segments with configurable size of payload data section
 - Each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
 - Applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
 - Receive message buffer
 - Transmit message buffer
- Individual message buffers can be reconfigured
 - Individual message buffers can be disabled safely
 - Disabled message buffers can be reconfigured
- Two independent receive FIFOs
 - One receive FIFO per channel
 - Up to 255 entries for each FIFO
 - Global frame ID filtering, based on both value/mask filters and range filters
 - Global channel ID filtering
 - Global message ID filtering for the dynamic segment
- Four configurable slot error counters
- Four dedicated slot status indicators
 - Used to observe slots without using receive message buffers

- Measured value indicators for clock synchronization
 - Internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- One absolute timer
- One timer that can be configured as absolute or relative
- SECEDED for protocol engine data RAM
- SEDDED for CHI lookup table RAM

51.1.6 Modes of operation

This section describes the basic operational power modes of the CC.

51.1.6.1 Disabled mode

The CC enters Disabled mode during hard reset or when the host clears the 'MEN' field in the Module Configuration Register (FR_MCR). The host can clear this field by writing '0' and only when the module is in *POC:default config* mode. The Disabled mode can be checked by reading the module enable field, MEN, in the *Module Configuration Register (FR_MCR)*.

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled mode* can be accessed for writing as stated in *Section 51.5, "Memory map and register description"*.

The application configures the CC by accessing the configuration fields in the *Module Configuration Register (FR_MCR)* as described in *Section 51.7.2.1, "Module initialization"*.

51.1.6.1.1 Leave Disabled mode

The CC leaves Disabled mode and enters Normal mode, when the application writes 1 to *FR_MCR[MEN]*.

Note: Once the CC is enabled, it cannot be disabled later.

51.1.6.2 Normal mode

In this mode, the CC is fully functional. The CC indicates that it is in Normal mode by asserting *FR_MCR[EN]*.

51.1.6.2.1 Enter Normal mode

This mode is entered when the application requests that the CC leave Disabled mode. If Normal mode is entered after leaving Disabled mode, the application has to perform the protocol initialization described in *Section 51.7.2.2, "Protocol initialization"* to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB fields in the *Module Configuration Register (FR_MCR)*, the corresponding FlexRay bus driver ports are enabled and driven.

51.1.6.3 System memory test

51.1.6.3.1 Bus Master Interface Functional Test for AMBA/AHB Bus

This section describes the test access to test the AMBA/AHB Bus Master Interface.

51.1.6.3.1.1 AMBA Read Access

This describes the sequence to initiate a amba read access

1. write word offset of address to read from into FR_PEDRAR[SYSMEMADDR]
2. and set the read/write indicator FR_PEDRAR[RW] to 1

The module clears the FR_PEDRAR[DAD] bit while access is running

The BMIF initiates a read from 64 bit-aligned byte address:

readaddr = ({SYSMEMADDR,0} + SMBA) & 64'hFFFFFFF8

The module sets the FR_PEDRAR[DAD] bit when access has finished

3. the data read and corresponds to {SYSMEMADDR,0} + SMBA are provided in the FR_PEDRDR register

51.1.6.3.1.2 AMBA Write Access (Prepare)

This describes how to provide data for the AMBA write access.

1. write 16-bit data to be written into FR_PEDRDR register
2. write 16-bit offset of address to be written to into FR_PEDRAR[SYSMEMADDR]
3. and set the read/write indicator FR_PEDRAR[RW] to 0

The module clears the FR_PEDRAR[DAD] bit.

The BMIF buffers this write request,

4. the module sets the FR_PEDRAR[DAD] bit when data are buffered

51.1.6.3.1.3 AMBA Write Access (Initiate)

The BMIF initiates the AMBA write access if any of sequences listed above was executed.
writeaddr = ({SYSMEMADDR,0} + SMBA) & 64'hFFFFFFF8.

Note: the read access to force the buffer write is not necessary in all cases, but suggested to have similar test sequences.

51.1.6.3.1.4 16 bit write initiate

A 16-bit write can be initiated as follows

- write to byte 0 and byte 1:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 00
initiate read from any address, to force buffer write
- write to byte 2 and byte 3:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 01
initiate read from any address, to force buffer write
- write to byte 4 and byte 5:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 10
initiate read from any address, to force buffer write
- write to byte 6 and byte 7:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 11
initiate read from any address, to force buffer write

51.1.6.3.1.5 32 bit write

- write to byte 0,1,2,3:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 00
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 01
initiate read from any address, to force buffer write
- write to byte 4,5,6,7:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 10
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 11
initiate read from any address, to force buffer write

51.1.6.3.1.6 64 bit write

- write to byte 0,1,2,3,4,5,6,7:
initiate read from any address, to empty the buffer
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 00
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 01
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 10
write with FR_PEDRAR[SYSMEMADDR[2:1]] = 2'h 11
initiate read from any address, to force buffer write

51.2 External Signal Description

This section lists and describes the CC signals connected to external pins. These signals are summarized in [Table 970](#) and described in detail in [Section 51.2.1, “Detailed signal description”](#).

Note: The off-chip FR_A_RX, FR_A_TX, and FR_A_TX_EN signals are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 970. External Signal Properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
FR_A_TX_EN	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
FR_B_TX_EN	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

51.2.1 Detailed signal description

This section provides a detailed description of the CC signals connected to external pins.

51.2.1.1 FR_A_RX—Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

51.2.1.2 FR_A_TX—Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

51.2.1.3 FR_A_TX_EN—Transmit Enable Channel A

The FR_A_TX_EN signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

51.2.1.4 FR_B_RX—Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

51.2.1.5 FR_B_TX—Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver.

51.2.1.6 FR_B_TX_EN—Transmit Enable Channel B

The FR_B_TX_EN signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

51.2.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0]—Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection, refer to [Section 51.6.16, “Strobe signal support”](#).

51.3 Controller Host Interface clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

- The first constraint corresponds to the number of utilized message buffers and is specified in [Section 51.7.5, “Number of usable message buffers”](#).
- The second constraint corresponds to the value of the TIMEOUT field in the [System Memory Access Time-Out Register \(FR_SYMATOR\)](#) and is specified in [Section 51.7.1.1, “Configure System Memory Access Timeout Register \(FR_SYMATOR\)”](#).

51.4 Protocol engine clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select field, CLKSEL, in the [Module Configuration Register \(FR_MCR\)](#).

Note: See the device clocking details for the exact clock sources used.

51.4.1 Oscillator clocking

If the protocol engine is clocked by the internal crystal oscillator, a 40 MHz crystal or CMOS-compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

51.4.2 PLL clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately to generate the 40 MHz and 180 degree phase-shifted 40 MHz clocks and provide them to the PE. For more details, see the clocking chapter of the device reference manual.

51.5 Memory map and register description

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU.

51.5.1 Memory map

The complete memory map of the CC is shown in [Table 971](#). The addresses presented here are the offsets relative to the CC base address, which is defined by the MCU address map.

Table 971. FlexRay memory map

Address Offset	Register Name	Access	Reset value	Section/ Page

51.5.2 Register descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities

51.5.2.1 Register Reset

Table 972. Register access conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
R*	Reserved bit or field, will not be changed. Application must not write any value different from the reset value.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A flag bit that can be read, is cleared by writing a one, writing 0 has no effect.
Reset Value	
0	Resets to zero.
1	Resets to one.
—	Not defined after reset and not affected by reset.

All registers except the [Message Buffer Cycle Counter Filter Registers \(FR_MBCCFRn\)](#), [Message Buffer Frame ID Registers \(FR_MBFIDRn\)](#), and [Message Buffer Index Registers \(FR_MBIDXRn\)](#) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are described in the detailed description of the register. The additional reset conditions are explained in [Table 973](#).

Table 973. Additional register reset conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes RUN command “0101” to the POCCMD field in the Protocol Operation Control Register (FR_POCR) .
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants a disable to the application by clearing the FR_MBCCSRn[EDS] bit.

51.5.2.2 Register write access

This section describes the write access restriction terms that apply to all registers.

51.5.2.2.1 Register write access restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in [Table 974](#). If, for a specific register field, none of the given write access conditions is fulfilled, any write attempt to this register field is ignored without any notification. The values of the fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 974. Register Write Access Restrictions

Condition	Indication	Description
Anytime	—	No write access restriction.
Disabled mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled mode.
Normal mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal mode.
POC:config	FR_PSR0[PROTSTATE] = <i>POC:config</i>	Write access only when protocol is in the <i>POC:config</i> state.
MB_DIS	FR_MBCCSR[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.
Functional Test Mode	FR_MCR[TMODE] = 1	Write access only when CC is in Functional Test Mode.

51.5.2.2.2 Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

51.5.2.2.3 Internal Register Access

The following memory-mapped registers are used to access multiple internal registers.

- [Strobe Signal Control Register \(FR_STBSCR\)](#)
- [Slot Status Selection Register \(FR_SSSR\)](#)
- [Slot Status Counter Condition Register \(FR_SSCCR\)](#)
- Receive Shadow Buffer Configuration Data

Each of these memory-mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If WMD is set to 0 during the write access, all fields of the internal register are updated. If WMD is set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

51.5.2.3 Module Version Register (FR_MVR)

Figure 940. Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Table 975. FR_MVR field descriptions

Field	Description
CHIVER	CHI Version Number —This field provides the version number of the controller host interface.
PEVER	PE Version Number —This field provides the version number of the protocol engine.

51.5.2.4 Module Configuration Register (FR_MCR)

Figure 941. Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Table 976. FR_MCR field descriptions

Field	Description
MEN	Module Enabl—This bit indicates whether or not the CC is in Disabled mode. The application requests that the CC leave Disabled mode by writing 1 to this bit. Before leaving Disabled mode, the application must configure the SCM, SBFF, CHB, CHA, TMODE, and BITRATE values. For details, see Section 51.1.6, “Modes of operation”. 0 Write: only during <i>POC:default config</i>, CC disable Read: CC disabled 1 Write: enable CC Read: CC enabled <i>Note: If the CC is enabled, it can only be disabled during mode: POC:default config</i>
SBFF	System Bus Failure Freeze—This bit controls the behavior of the CC in case of a system bus failure. 0 Continue normal operation 1 Transition to Freeze mode
SCM	Single Channel Device Mode—This control bit defines the channel device mode of the CC as described in Section 51.6.10, “Channel device modes”. 0 CC works in Dual-Channel Device mode 1 CC works in Single-Channel Device mode
CHB CHA	Channel Enable—protocol related parameter: <i>pChannels</i> The semantic of these control bits depends on the channel device mode controlled by the SCM bit and is given Table 977.
SFFE	Synchronization Frame Filter Enable—This bit controls the filtering for received synchronization frames. For details see Section 51.6.15, “Sync frame filtering”. 0 Synchronization frame filtering disabled 1 Synchronization frame filtering enabled
ECCE	ECC Functionality Enable—This bit controls the ECC memory error detection functionality. For details see Section 51.6.24, “Memory content error detection”. 0 ECC functionality (injection, detection, reporting, response) disabled 1 ECC functionality enabled
TMODE	Test Mode—This control bit is used to enable and disable the functional test mode. 0 Functional Test Mode disabled 1 Functional Test Mode enabled
FUM	FIFO Update Mode—This bit controls the FIFO update behavior when the interrupt flags FR_GIFER[FAFAIF] and FR_GIFER[FAFBIF] are written by the application (see Section 51.6.9.8, “FIFO update”). 0 FIFOA/FIFOB is updated on writing 1 to FR_GIFER[FAFAIF] /FR_GIFER[FAFBIF] 1 FIFOA/FIFOB is <i>not</i> updated on writing 1 to FR_GIFER[FAFAIF]/FR_GIFER[FAFBIF]
FAM	FIFO Address Mode—This bit controls the location of the system memory base address for the FIFOs (see Section 51.6.9.2, “FIFO configuration”). 0 FIFO Base Address located in System Memory Base Address Register (FR_SYMBADR) 1 FIFO Base Address located in Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)

Table 976. FR_MCR field descriptions

Field	Description
CLKSEL	Protocol Engine Clock Source Select —This bit is used to select the clock source for the protocol engine. 0 PE clock source is generated by on-chip crystal oscillator. 1 PE clock source is generated by on-chip PLL.
BITRATE	FlexRay Bus Bit Rate —This field defines the FlexRay bus bit rate. 000 10.0 Mbit/s 001 5.0 Mbit/s 010 2.5 Mbit/s 011 8.0 Mbit/s 100 Reserved 101 Reserved 110 Reserved 111 Reserved

Table 977. FlexRay channel selection

SCM	CHB	CHA	Description
Dual Channel Device modes			
0	0	0	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN not driven by CC ports FR_B_RX, FR_B_TX, and FR_A_TX_EN not driven by CC
	0	1	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN driven by CC—connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and FR_A_TX_EN not driven by CC
	1	0	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN not driven by CC ports FR_B_RX, FR_B_TX, and FR_A_TX_EN driven by CC—connected to FlexRay channel B
	1	1	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN driven by CC—connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and FR_A_TX_EN driven by CC—connected to FlexRay channel B
Single Channel Device mode			
1	0	0	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN not driven by CC ports FR_B_RX, FR_B_TX, and FR_A_TX_EN not driven by CC
	0	1	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN driven by CC—connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and FR_A_TX_EN not driven by CC
	1	0	ports FR_A_RX, FR_A_TX, and FR_A_TX_EN driven by CC—connected to FlexRay channel B ports FR_B_RX, FR_B_TX, and FR_A_TX_EN not driven by CC
	1	1	Reserved

51.5.2.5 System Memory Base Address Register (FR_SYMBADR)

Figure 942. System Memory Base Address High Register (FR_SYMBADHR)

Figure 943. System Memory Base Address Low Register (FR_SYMBADLR)

Note: The system memory base address must be set before the CC is enabled.

The system memory base address registers define the base address of the FlexRay memory area within the system memory. The base address is used by the bus master interface (BMIF) to calculate the physical memory address for system memory accesses.

Table 978. FR_SYMBADR field descriptions

Field	Description
SMBA	System Memory Base Address —This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if FR_MCR[FAM] is set to 1. It defines as a byte address.

51.5.2.6 Strobe Signal Control Register (FR_STBSCR)

Figure 944. Strobe Signal Control Register (FR_STBSCR)

This register is used to assign the individual protocol timing-related strobe signals given in [Table 980](#) to the external strobe ports. Each strobe signal can be assigned to at most one strobe port. Each write access to registers overwrites the previously-written ENB and STBPSEL values for the signal indicated by SEL. If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR

and presented at the strobe port. If no strobe signal is assigned to a strobe port, the strobe port carries logic 0. For more detailed and timing information refer to [Section 51.6.16](#), “Strobe signal support.”

Note: In Single-Channel Device mode, channel B-related strobe signals are undefined and should not be assigned to the strobe ports.

Table 979. FR_STBSCR field descriptions

Field	Description
WMD	Write Mode —This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
SEL	Strobe Signal Select —This control field selects one of the strobe signals given in Table 980 to be enabled or disabled and assigned to one of the four strobe ports given in Table 980 .
ENB	Strobe Signal Enable —The control bit is used to enable and disable the strobe signal selected by STBSSEL. 0 Strobe signal is disabled and not assigned to any strobe port. 1 Strobe signal is enabled and assigned to the strobe port selected by STBPSEL.
STBPSEL	Strobe Port Select —This field selects the strobe port that the strobe signal selected by the SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00 Assign selected signal to FR_DBG[0]. 01 Assign selected signal to FR_DBG[1]. 10 Assign selected signal to FR_DBG[2]. 11 Assign selected signal to FR_DBG[3].

Table 980. Strobe signal mapping

SEL		Description	Channel	Type	Offset ⁽¹⁾	Reference
dec	hex					
0	0x0	Arm	—	value	+1	MT start
1	0x1	mt	—	value	+1	MT start
2	0x2	Cycle start	—	pulse	0	MT start
3	0x3	Minislot start	—	pulse	0	MT start
4	0x4	Slot start	A	pulse	0	MT start
5	0x5		B			
6	0x6	Receive data after glitch filtering	A	value	+4	FR_A_RX
7	0x7		B			FR_B_RX
8	0x8	Channel idle indicator	A	level	+5	FR_A_RX
9	0x9		B			FR_B_RX
10	0xA	Syntax error detected	A	pulse	+4	FR_A_RX
11	0xB		B			FR_B_RX
12	0xC	Content error detected	A	level	+4	FR_A_RX
13	0xD		B			FR_B_RX

Table 980. Strobe signal mapping

SEL		Description	Channel	Type	Offset ⁽¹⁾	Reference

14	0xE	Receive FIFO almost-full interrupt signals	A	value	n.a.	RX FIFO A Almost Full Interrupt
15	0xF		B			RX FIFO B Almost Full Interrupt

1. Given in PE clock cycles

51.5.2.7 Message Buffer Data Size Register (FR_MBDSR)

Figure 945. Message Buffer Data Size Register (FR_MBDSR)

Base + 0x000C

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Table 981. FR_MBDSR field descriptions

Field	Description
MBSEG2DS	Message Buffer Segment 2 Data Size —The field defines the size of the message buffer data section in two-byte entities for message buffers within the <i>second</i> message buffer segment.
MBSEG1DS	Message Buffer Segment 1 Data Size —The field defines the size of the message buffer data section in two-byte entities for message buffers within the <i>first</i> message buffer segment.

51.5.2.8 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Figure 946. Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Base + 0x000E

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								0							
W																
Reset	0	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1

This register defines the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Table 982. FR_MBSSUTR Field Descriptions

Field	Description
LAST_MB_SEG1	Last Message Buffer In Segment 1—This field defines the message buffer number of the last individual message buffer that is assigned to the <i>first</i> message buffer segment. The individual message buffers in the <i>first</i> segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn with $n \leq \text{LAST_MB_SEG1}$. The first message buffer segment contains $\text{LAST_MB_SEG1} + 1$ individual message buffers. <i>Note: The first message buffer segment contains at least one individual message buffer.</i> The individual message buffers in the <i>second</i> message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with $\text{LAST_MB_SEG1} < n < 128$. <i>Note: If $\text{LAST_MB_SEG1} = 127$, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.</i>
LAST_MB_UTIL	Last Message Buffer Utilized—This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number $n \leq \text{LAST_MB_UTIL}$. <i>Note: If $\text{LAST_MB_UTIL} = \text{LAST_MB_SEG1}$, all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.</i>

51.5.2.9 PE DRAM Access Register (FR_PEDRAR)

Figure 947. PE DRAM Access Register (FR_PEDRAR)

In Functional Test mode this register is used to setup read and write operations to the system memory.

The FR_PEDRAR is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this register initiates a read or write operation on the PE DRAM. The access done status bit, DAD, is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRAR is written into the PE DRAM, read back from the PE DRAM, and are stored into the FR_PEDRAR.

In case of an PE DRAM read access, the requested data is read from PE DRAM and stored into the FR_PEDRAR.

For a detailed description, refer to [Section 51.6.24, “Memory content error detection”](#)

Table 983. FR_PEDRAR field descriptions

Field	Description
INST	PE DRAM Access Instruction —This field defines the operation to be executed on the PE DRAM. 0011 PE DRAM write: Write FR_PEDRDR[DATA] to PE DRAM address ADDR (16 bit) 0101 PE DRAM read: Read Data from PE DRAM address ADDR (16 bit) into FR_PEDRDR[DATA] other reserved
ADDR	PE DRAM Access Address —This field defines the address in the PE DRAM to be written to or read from.
DAD	PE DRAM Access Done —This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done
SYSTEMADDR	Functional Test Mode Only System Memory Address — This field defines the system memory address to be written to or read from.
RW	Functional Test Mode Only Debug Read Write Selector — This control bit defines the access direction for the system memory access. 0 system memory write access 1 system memory read access

51.5.2.10 PE DRAM Data Register (FR_PEDRDR)

Figure 948. PE DRAM Data Register (FR_PEDRDR)

This register provides the data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

51.5.2.11 Protocol Operation Control Register (FR_POCR)

Figure 949. Protocol Operation Control Register (FR_POCR)

Base + 0x0014												Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	EOC_AP		ERC_AP		BSY	0	0	0	POCCMD			
W	WME								WMC							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The application uses this register to issue:

- Protocol control commands
- External clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see [Section 51.7.6, “Protocol Control Command Execution”](#).

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to [Section 51.6.11, “External clock synchronization”](#).

Table 984. FR_POCR Field Descriptions

Field	Description
WME	Write Mode External Correction —This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write 1 No write to EOC_AP and ERC_AP fields on register write
EOC_AP	External Offset Correction Application —This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29) . 00 Do not apply external offset correction value. 01 Reserved. 10 Subtract external offset correction value 11 Add external offset correction value
ERC_AP	External Rate Correction Application —This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21) . 00 Do not apply external rate correction value 01 Reserved 10 Subtract external rate correction value 11 Add external rate correction value

Table 984. FR_POCR Field Descriptions

Field	Description
BSY	Protocol Control Command Write Busy —This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the <i>CHI Error Flag Register (FR_CHIERFR)</i> , and will not change the value of the POCCMD field. 0 Command write idle, command accepted and ready to receive new protocol command 1 Command write busy, command not yet accepted, not ready to receive new protocol command
WMC	Write Mode Command —This bit controls the write mode of the POCCMD field. 0 Write to POCCMD field on register write 1 Do not write to POCCMD field on register write
POCCMD	Protocol Control Command —The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTAR—Immediately activate capability of node to cold start cluster. 0001 ALL_SLOTS—Delayed ⁽¹⁾ transition to the All Slots Transmission mode. 0010 CONFIG—Immediately transition to the <i>POC:config</i> state. 0011 FREEZE—Immediately transition to the <i>POC:halt</i> state. 0100 READY, CONFIG_COMPLETE—Immediately transition to the <i>POC:ready</i> state. 0101 RUN—Immediately transition to the <i>POC:startup start</i> state. 0110 DEFAULT_CONFIG—Immediately transition to the <i>POC:default config</i> state. 0111 HALT—Delayed transition to the <i>POC:halt</i> state 1000 WAKEUP—Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

1. Delayed means on completion of current communication cycle.

51.5.2.12 Global Interrupt Flag and Enable Register (FR_GIFER)

Figure 950. Global Interrupt Flag and Enable Register (FR_GIFER)

Base + 0x0016				In Functional Test Mode writing 1 toggles the interrupt flags.								Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MIF	PRIF	CHIF	WUIF	FAFBIF	FAFAIF	RBIF	TBIF	MIE	PRIE	CHIE	WUIE	FAFBIE	FAFAIE	RBIE	TBIE
W				w1c	w1c	w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register controls some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables. The generation

scheme for these flags is depicted in [Figure 1098](#). For more details on interrupt generation, see [Section 51.6.20, “Interrupt support](#). These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Table 985. FR_GIFER field descriptions

Field	Description
MIF	Module Interrupt Flag —This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set
PRIF	Protocol Interrupt Flag —This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set
CHIF	CHI Interrupt Flag —This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the CHI error interrupt enable bit FR_GIFER[CHIE] are set. 0 All CHI error flags are equal to 0 or the CHI error interrupt is disabled 1 At least one CHI error flag and the CHI error interrupt enable are is set
WUPIF	Wakeup Interrupt Flag —This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3) . 0 No wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus
FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag —This interrupt flag is set when one of the following events occurs: a) The current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR) , and the CC writes a received message into the FIFO B, or b) The current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO B almost full event has occurred
FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag —This interrupt flag is set when one of the following events occurs: a) The current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR) , and the CC writes a received message into the FIFO A, or b) The current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 No such event 1 FIFO A almost full event has occurred

Table 985. FR_GIFER field descriptions (continued)

Field	Description
RBIF	Receive Message Buffer Interrupt Flag—This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application can not clear this interrupt flag directly; instead, it is cleared by the CC when all of the MBIF interrupt flags of the individual receive message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual receive message buffers has the MBIF and MBIE flag set 1 At least one individual receive message buffer has the MBIF and MBIE flag set
TBIF	Transmit Message Buffer Interrupt Flag—This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the MBIF interrupt flag and the MBIE interrupt enable bit in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application cannot clear this interrupt flag directly; instead, this interrupt flag is cleared by the CC when all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application, or when the application has cleared the related MBIE interrupt enable bit. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set 1 At least one individual transmit message buffer has the MBIF and MBIE flag set
MIE	Module Interrupt Enable—This bit controls whether the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
PRIE	Protocol Interrupt Enable—This bit controls whether the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
CHIE	CHI Interrupt Enable—This bit controls whether the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
WUPIE	Wakeup Interrupt Enable—This bit controls whether the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
FAFBIE	Receive FIFO Channel B Almost Full Interrupt Enable—This bit controls whether the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
FAFAIE	Receive FIFO Channel A Almost Full Interrupt Enable—This bit controls whether the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

Table 985. FR_GIFER field descriptions (continued)

Field	Description
RBIE	Receive Message Buffer Interrupt Enable —This bit controls whether the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
TBIE	Transmit Message Buffer Interrupt Enable —This bit controls whether the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

51.5.2.13 Protocol Interrupt Flag Register 0 (FR_PIFR0)

Figure 951. Protocol Interrupt Flag Register 0 (FR_PIFR0)

Base + 0x0018				In Functional Test Mode writing 1 toggles the interrupt flags.								Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FATL _IF	INTL _IF	ILCF _IF	CSA _IF	MRC _IF	MOC _IF	CCL _IF	MXS _IF	MTX _IF	LTXB _IF	LTX A_IF	TBVB _IF	TBVA _IF	TI2 _IF	TI1 _IF	CYS _IF
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register holds one set of the protocol-related individual interrupt flags.

Table 986. FR_PIFR0 field descriptions

Field	Description
FATL_IF	Fatal Protocol Error Interrupt Flag —This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the <i>POC:halt</i> state immediately. The fatal protocol errors are: 1) <i>pLatestTx</i> violation, as described in the MAC process of the FlexRay protocol 2) transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event 1 Fatal protocol error detected
INTL_IF	Internal Protocol Error Interrupt Flag —This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the <i>POC:halt</i> state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event 1 Internal protocol error detected

Table 986. FR_PIFR0 field descriptions (continued)

Field	Description
ILCF_IF	Illegal Protocol Configuration Interrupt Flag—This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the <i>POC:halt</i> state immediately. The protocol engine checks the <i>listen_timeout</i> value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of <i>listen_timeout</i> is equal to 0, the protocol configuration setting is considered as illegal. 0 No such event 1 Illegal protocol configuration detected
CSA_IF	Cold Start Abort Interrupt Flag—This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the <i>coldstart_attempts</i> field in the Protocol Configuration Register 3 (FR_PCR3). 0 No such event 1 Cold start aborted and no more coldstart attempts allowed
MRC_IF	Missing Rate Correction Interrupt Flag—This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
MOC_IF	Missing Offset Correction Interrupt Flag—This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event 1 Insufficient number of measurements for offset correction detected
CCL_IF	Clock Correction Limit Reached Interrupt Flag—This flag is set when the internal calculated offset or rate calculation values have reached or exceeded their configured thresholds as given by the <i>offset_coorection_out</i> field in the Protocol Configuration Register 9 (FR_PCR9) and the <i>rate_correction_out</i> field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event 1 Offset or rate correction limit reached
MXS_IF	Max Sync Frames Detected Interrupt Flag—This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the <i>node_sync_max</i> field in the Protocol Configuration Register 30 (FR_PCR30). 0 No such event. 1 More than <i>node_sync_max</i> sync frames detected <i>Note: Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account</i>
MTX_IF	Media Access Test Symbol Received Interrupt Flag—This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event 1 MTS symbol received
LTXB_IF	pLatestTx Violation on Channel B Interrupt Flag—This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the <i>pLatestTx</i> violation, as described in the MAC process of the FlexRay protocol. 0 No such event 1 <i>pLatestTx</i> violation occurred on channel B

Table 986. FR_PIFR0 field descriptions (continued)

Field	Description
LTXA_IF	<i>pLatestTx</i> Violation on Channel A Interrupt Flag —This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the <i>pLatestTx</i> violation as described in the MAC process of the FlexRay protocol. 0 No such event 1 <i>pLatestTx</i> violation occurred on channel A
TBVB_IF	Transmission across boundary on channel B Interrupt Flag —This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel B
TBVA_IF	Transmission across boundary on channel A Interrupt Flag —This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event 1 Transmission across boundary violation occurred on channel A
TI2_IF	Timer 2 Expired Interrupt Flag —This flag is set whenever timer 2 expires. 0 No such event 1 Timer 2 has reached its time limit
TI1_IF	Timer 1 Expired Interrupt Flag —This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
CYS_IF	Cycle Start Interrupt Flag —This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started.

51.5.2.14 Protocol Interrupt Flag Register 1 (FR_PIFR1)

Figure 952. Protocol Interrupt Flag Register 1 (FR_PIFR1)

Base + 0x001A				In Functional Test Mode writing 1 toggles the interrupt flags.								Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EMC_IF	IPC_IF	PEC_F_IF	PSC_IF	SSI3_IF	SSI2_IF	SSI1_IF	SSI0_IF	0	0	EVT_IF	ODT_IF	0	0	0	0
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c			w1c	w1c				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The register holds one set of the protocol-related individual interrupt flags.

Table 987. FR_PIFR1 field descriptions

Field	Description
EMC_IF	Error Mode Changed Interrupt Flag —This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC. 0 No such event 1 ERRMODE field changed
IPC_IF	Illegal Protocol Control Command Interrupt Flag —This flag is set when the PE tries to execute a protocol control command that was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR) , and detects that this protocol control command is not allowed in the current protocol state. In this case, the command is not executed. For more details, see Section 51.7.6, “Protocol Control Command Execution” . 0 No such event 1 Illegal protocol control command detected
PECF_IF	Protocol Engine Communication Failure Interrupt Flag —This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event 1 Protocol Engine Communication Failure detected
PSC_IF	Protocol State Changed Interrupt Flag —This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event 1 Protocol state changed
SSI3_IF SSI2_IF SSI1_IF SSI0_IF	Slot Status Counter Incremented Interrupt Flag —Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCR0–FR_SSCR3) is incremented. 0 No such event 1 The corresponding slot status counter has incremented
EVT_IF	Even Cycle Table Written Interrupt Flag —This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the even cycle. 0 No such event 1 Sync frame measurement table written
ODT_IF	Odd Cycle Table Written Interrupt Flag —This flag is set if the CC has written the sync frame measurement/ID tables into the FlexRay memory area for the odd cycle. 0 No such event 1 Sync frame measurement table written

51.5.2.15 Protocol Interrupt Enable Register 0 (FR_PIER0)

Figure 953. Protocol Interrupt Enable Register 0 (FR_PIER0)

Base + 0x001C

Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FATL	INTL	ILCF	CSA	MRC	MOC	CCL	MXS	MTX	LTXB	LTXA	TBVB	TBVA	TI2	TI1	CYS

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines whether or not the individual interrupt flags defined in the [Protocol Interrupt Flag Register 0 \(FR_PIFR0\)](#) can generate a protocol interrupt request.

Table 988. FR_PIER0 field descriptions

Field	Description
FATL_IE	Fatal Protocol Error Interrupt Enable —This bit controls FATL_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
INTL_IE	Internal Protocol Error Interrupt Enable —This bit controls INTL_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
ILCF_IE	Illegal Protocol Configuration Interrupt Enable —This bit controls ILCF_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
CSA_IE	Cold Start Abort Interrupt Enable —This bit controls CSA_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
MRC_IE	Missing Rate Correction Interrupt Enable —This bit controls MRC_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
MOC_IE	Missing Offset Correction Interrupt Enable —This bit controls MOC_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
CCL_IE	Clock Correction Limit Reached Interrupt Enable —This bit controls CCL_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
MXS_IE	Max Sync Frames Detected Interrupt Enable —This bit controls MXS_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
MTX_IE	Media Access Test Symbol Received Interrupt Enable —This bit controls MTX_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
LTXB_IE	<i>pLatestTx</i> Violation on Channel B Interrupt Enable —This bit controls LTXB_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled
LTXA_IE	<i>pLatestTx</i> Violation on Channel A Interrupt Enable —This bit controls LTXA_IF interrupt request generation. 0interrupt request generation disabled 1interrupt request generation enabled

Table 988. FR_PIER0 field descriptions

Field	Description
TBVB_IE	Transmission across boundary on channel B Interrupt Enable —This bit controls TBVB_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
TBVA_IE	Transmission across boundary on channel A Interrupt Enable —This bit controls TBVA_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
TI2_IE	Timer 2 Expired Interrupt Enable —This bit controls TI1_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
TI1_IE	Timer 1 Expired Interrupt Enable —This bit controls TI1_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
CYS_IE	Cycle Start Interrupt Enable —This bit controls CYC_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled

51.5.2.16 Protocol Interrupt Enable Register 1 (FR_PIER1)

Figure 954. Protocol Interrupt Enable Register 1 (FR_PIER1)

Base + 0x001E								Write: Anytime								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines whether or not the individual interrupt flags defined in [Protocol Interrupt Flag Register 1 \(FR_PIFR1\)](#) can generate a protocol interrupt request.

Table 989. FR_PIER1 field descriptions

Field	Description
EMC_IE	Error Mode Changed Interrupt Enable —This bit controls EMC_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
IPC_IE	Illegal Protocol Control Command Interrupt Enable —This bit controls IPC_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled

Table 989. FR_PIER1 field descriptions

Field	Description
PECF_IE	Protocol Engine Communication Failure Interrupt Enable —This bit controls PECF_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
PSC_IE	Protocol State Changed Interrupt Enable —This bit controls PSC_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
SSI3_IE SSI2_IE SSI1_IE SSI0_IE	Slot Status Counter Incremented Interrupt Enable —This bit controls SSI[3:0]_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
EVT_IE	Even Cycle Table Written Interrupt Enable —This bit controls EVT_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled
ODT_IE	Odd Cycle Table Written Interrupt Enable —This bit controls ODT_IF interrupt request generation. 0 interrupt request generation disabled 1 interrupt request generation enabled

51.5.2.17 CHI Error Flag Register (FR_CHIERFR)

Figure 955. CHI Error Flag Register (FR_CHIERFR)

Base + 0x0020				In Functional Test Mode writing 1 toggles the interrupt flags.								Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FRLB _EF	FRLA _EF	PCMI _EF	FOV B_EF	FOV A_EF	MBS _EF	MBU _EF	LCK _EF	0	SBC F_EF	FID _EF	DPL _EF	SPL _EF	NML _EF	NMF _EF	ILSA _EF
W	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c		w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register holds the CHI-related error flags. The interrupt generation for each of these error flags is controlled by the CHI interrupt enable bit, CHIE, in the [Global Interrupt Flag and Enable Register \(FR_GIFER\)](#).

Table 990. FR_CHIERFR field descriptions

Field	Description
FRLB_EF	Frame Lost Channel B Error Flag—This flag is set if a complete frame was received on channel B but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such event 1 Frame lost on channel B detected
FRLA_EF	Frame Lost Channel A Error Flag—This flag is set if a complete frame was received on channel A but it could not be stored in the selected individual message buffer because the message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected
PCMI_EF	Protocol Command Ignored Error Flag—This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCCR) while the BSY flag is equal to 1. In this case, the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
FOVB_EF	Receive FIFO Overrun Channel B Error Flag—This flag is set when an overrun of the FIFO for channel B has occurred. This error occurs if a semantically valid frame was received on channel B and matches all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
FOVA_EF	Receive FIFO Overrun Channel A Error Flag—This flag is set when an overrun of the FIFO for channel A has occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
MBS_EF	Message Buffer Search Error Flag—This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 131 is detected in the FR_MBIDXR[MBIDX] field of a found message buffer or in one of the FR_RSBIR[RSBIDX] fields. Refer to Section 51.6.7.4, "Message buffer search error" for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected
MBU_EF	Message Buffer Utilization Error Flag—This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled

Table 990. FR_CHIERFR field descriptions (continued)

Field	Description
LCK_EF	Lock Error Flag —This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again. 0 No such error 1 Lock error detected
SBCF_EF	System Bus Communication Failure Error Flag —This flag is set if a system bus access was not finished within the required amount of time (see Section 51.6.19.1.2, “System bus access timeout”). 0 No such event 1 System bus access not finished in time
FID_EF	Frame ID Error Flag —This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register. 0 No such error occurred 1 Frame ID error occurred
DPL_EF	Dynamic Payload Length Error Flag —This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24) . 0 No such error occurred 1 Dynamic payload length error occurred
SPL_EF	Static Payload Length Error Flag —This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19) . 0 No such error occurred 1 Static payload length error occurred
NML_EF	Network Management Length Error Flag —This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR) . In this case, the received part of the Network Management Vector will be used to update the Network Management Vector. 0 No such error occurred 1 Network management length error occurred
NMF_EF	Network Management Frame Error Flag —This flag is set if a received message in the static segment with a Preamble Indicator flag (PP) asserted has its Null Frame indicator flag (NF) asserted as well. In this case, the Global Network Management Registers (see Section 51.5.2.39, “Network Management Vector Registers (FR_NMVR0–FR_NMVR5)”) are not updated. 0 No such error occurred 1 Network management frame error occurred
ILSA_EF	Illegal System Bus Address Error Flag —This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (see Section 51.6.19.1.1, “System bus illegal address access”). 0 No such event 1 Illegal system bus address accessed

51.5.2.18 Message Buffer Interrupt Vector Register (FR_MBIVEC)

Figure 956. Message Buffer Interrupt Vector Register (FR_MBIVEC)

Base + 0x0022

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	TBIVEC							0	RBIVEC						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their MBIF interrupt status flag and MBIE interrupt enable bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Table 991. FR_MBIVEC field descriptions

Field	Description
TBIVEC	Transmit Buffer Interrupt Vector —This field provides the number of the lowest numbered enabled transmit message buffer that has its MBIF interrupt status flag and its MBIE interrupt enable bit set. If there is no transmit message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.
RBIVEC	Receive Buffer Interrupt Vector —This field provides the message buffer number of the lowest numbered receive message buffer that has its MBIF interrupt flag and its MBIE interrupt enable bit asserted. If there is no receive message buffer with the MBIF interrupt status flag and the MBIE interrupt enable bits asserted, the value in this field is set to 0.

51.5.2.19 Channel A Status Error Counter Register (FR_CASERCR)

Figure 957. Channel A Status Error Counter Register (FR_CASERCR)

Base + 0x0024

Additional Reset: RUN Command

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	STATUS_ERR_CNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits [vSS!SyntaxError](#), [vSS!ContentError](#), [vSS!BViolation](#), and [vSS!TxConflict](#). The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see [Section 51.6.18, “Slot status monitoring”](#).

Table 992. FR_CASERCR Field Descriptions

Field	Description
STATUS_ERR_CNT	Channel Status Error Counter — This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

51.5.2.20 Channel B Status Error Counter Register (FR_CBSECR)

Figure 958. Channel B Status Error Counter Register (FR_CBSECR)

This register provides the channel status error counter for channel B. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the network idle time (NIT). The slot status vector contains the four protocol-related error indicator bits [vSS!SyntaxError](#), [vSS!ContentError](#), [vSS!BViolation](#), and [vSS!TxConflict](#). The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see [Section 51.6.18, “Slot status monitoring”](#).

Table 993. FR_CBSECR field descriptions

Field	Description
STATUS_ERR_CNT	Channel Status Error Counter —This field provides the current channel status error count. The counter value is updated within the first macrotick of the following slot or segment.

51.5.2.21 Protocol Status Register 0 (FR_PSR0)

Figure 959. Protocol Status Register 0 (FR_PSR0)

This register provides information about the current protocol status.

Table 994. FR_PSR0 field descriptions

Field	Description
ERRMODE	Error Mode —protocol-related variable: <i>vPOC!ErrorMode</i> . This field indicates the error mode of the protocol. 00 ACTIVE 01 PASSIVE 10 COMM_HALT 11 Reserved
SLOTMODE	Slot Mode —protocol-related variable: <i>vPOC!SlotMode</i> . This field indicates the slot mode of the protocol. 00 SINGLE 01 ALL_PENDING 10 ALL 11 Reserved
PROTSTATE	Protocol State —protocol-related variable: <i>vPOC!State</i> . This field indicates the state of the protocol. 000 <i>POC:default config</i> 001 <i>POC:config</i> 010 <i>POC:wakeup</i> 011 <i>POC:ready</i> 100 <i>POC:normal passive</i> 101 <i>POC:normal active</i> 110 <i>POC:halt</i> 111 <i>POC:startup</i>
STARTUP STATE	Startup State —protocol-related variable: <i>vPOC!StartupState</i> . This field indicates the current sub-state of the startup procedure. 0000 Reserved 0001 Reserved 0010 <i>POC:coldstart collision resolution</i> 0011 <i>POC:coldstart listen</i> 0100 <i>POC:integration consistency check</i> 0101 <i>POC:integrationi listen</i> 0110 Reserved 0111 <i>POC:initialize schedule</i> 1000 Reserved 1001 Reserved 1010 <i>POC:coldstart consistency check</i> 1011 Reserved 1100 Reserved 1101 <i>POC:integration coldstart check</i> 1110 <i>POC:coldstart gap</i> 1111 <i>POC:coldstart join</i>
WAKEUP STATUS	Wakeup Status —protocol-related variable: <i>vPOC!WakeupStatus</i> . This field provides the outcome of the execution of the wakeup mechanism. 000 UNDEFINED 001 RECEIVED_HEADER 010 RECEIVED_WUP 011 COLLISION_HEADER 100 COLLISION_WUP 101 COLLISION_UNKNOWN 110 TRANSMITTED 111 Reserved

51.5.2.22 Protocol Status Register 1 (FR_PSR1)

Figure 960. Protocol Status Register 1 (FR_PSR1)

Base + 0x002A				Additional Reset: CSAA, CSP, CPN: RUN Command								Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W	w1c															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 995. FR_PSR1 field descriptions

Field	Description
CSAA	Cold Start Attempt Aborted Flag —protocol-related event: ‘set coldstart abort indicator in CHI.’ This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
CSP	Leading Cold Start Path —This status bit is set when the CC has reached the <i>POC:normal active</i> state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 <i>POC:normal active</i> reached from <i>POC:startup</i> state via leading cold start path
REMCSAT	Remaining Coldstart Attempts —protocol-related variable: <i>vRemainingColdstartAttempts</i> . This field provides the number of remaining cold start attempts that the CC will execute.
CPN	Leading Cold Start Path Noise —protocol-related variable: <i>vPOC!ColdstartNoise</i> . This status bit is set if the CC has reached the <i>POC:normal active</i> state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 <i>POC:normal active</i> state was reached from <i>POC:startup</i> state via noisy leading cold start path
HHR	Host Halt Request Pending —protocol related variable: <i>vPOC!CHI!HaltRequest</i> . This status bit is set when CC receives the HALT command from the application via the <i>Protocol Operation Control Register (FR_POCR)</i> . The CC clears this status bit after a hard reset condition or when the protocol is in the <i>POC:default config</i> state. 0 No such event 1 HALT command received
FRZ	Freeze Occurred —protocol related variable: <i>vPOC!Freeze</i> . This status bit is set when the CC has reached the <i>POC:halt</i> state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the <i>POC:default config</i> state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
APTAC	Allow Passive to Active Counter —protocol-related variable: <i>vPOC!vAllowPassivetoActive</i> . This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the <i>POC:normal passive</i> state due to an application-configured delay to enter <i>POC:normal active</i> state. This delay is defined by the allow_passive_to_active field in <i>Protocol Configuration Register 12 (FR_PCR12)</i> .

51.5.2.23 Protocol Status Register 2 (FR_PSR2)

Figure 961. Protocol Status Register 2 (FR_PSR2)

Base + 0x002C				Additional Reset: RUN Command												
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	NBVB	NSEB	STCB	SBVB	SSEB	MTB	NBVA	NSEA	STCA	SBVA	SSEA	MTA	CLKCORRFAILCNT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides a snapshot of status information about the network idle time (NIT), the symbol window, and the clock synchronization. The NIT-related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The symbol-window-related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol-window-related status bits remain in their reset state. The clock synchronization-related CLKCORRFAILCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Table 996. FR_PSR2 field descriptions

Field	Description
NBVB	NIT Boundary Violation on Channel B —protocol-related variable: vSS!BViolation for NIT on channel B. This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
NSEB	NIT Syntax Error on Channel B —protocol-related variable: vSS!SyntaxError for NIT on channel B. This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
STCB	Symbol Window Transmit Conflict on Channel B —protocol-related variable: vSS!TxConflict for symbol window on channel B. This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
SBVB	Symbol Window Boundary Violation on Channel B —protocol-related variable: vSS!BViolation for symbol window on channel B. This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
SSEB	Symbol Window Syntax Error on Channel B —protocol related variable: vSS!SyntaxError for symbol window on channel B. This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected

Table 996. FR_PSR2 field descriptions (continued)

Field	Description
MTB	Media Access Test Symbol MTS Received on Channel B —protocol-related variable: vSS!ValidMTS for Symbol Window on channel B. This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
NBVA	NIT Boundary Violation on Channel A —protocol-related variable: vSS!BViolation for NIT on channel A. This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
NSEA	NIT Syntax Error on Channel A —protocol-related variable: vSS!SyntaxError for NIT on channel A. This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected
STCA	Symbol Window Transmit Conflict on Channel A —protocol related variable: vSS!TxConflict for symbol window on channel A. This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
SBVA	Symbol Window Boundary Violation on Channel A —protocol-related variable: vSS!BViolation for symbol window on channel A. This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
SSEA	Symbol Window Syntax Error on Channel A —protocol-related variable: vSS!SyntaxError for symbol window on channel A. This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected
MTA	Media Access Test Symbol MTS Received on Channel A —protocol-related variable: vSS!ValidMTS for symbol window on channel A. This status bit is set if the Media Access Test Symbol (MTS) was received in the symbol window on channel A. 0 No such event 1 MTS symbol received
CLKCORR-FAILCNT	Clock Correction Failed Counter —protocol -elated variable: vClockCorrectionFailed . This field provides the number of consecutive even/odd communication cycle pairs that have passed without a clock synchronization offset or rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either <code>max_without_clock_correction_fatal</code> or <code>max_without_clock_correction_passive</code> as defined in Protocol Configuration Register 8 (FR_PCR8) . The CC resets this counter on a hard reset condition, when the protocol enters the POC:normal active state, or when both the rate and offset correction terms have been calculated successfully.

51.5.2.24 Protocol Status Register 3 (FR_PSR3)

Figure 962. Protocol Status Register 3 (FR_PSR3)

Base + 0x002E				Additional Reset: RUN Command								Write: Normal mode				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W			w1c	w1c	w1c	w1c	w1c	w1c			w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception. It provides accrued information for the symbol window, the NIT, and the wakeup status.

Table 997. FR_PSR3 field descriptions

Field	Description
WUB	Wakeup Symbol Received on Channel B —This flag is set when a wakeup symbol was received on channel B. 0 No wakeup symbol received 1 Wakeup symbol received
ABVB	Aggregated Boundary Violation on Channel B —This flag is set when a boundary violation was detected on channel B. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
AACB	Aggregated Additional Communication on Channel B —This flag is set when at least one valid frame was received on channel B in a slot that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
ACEB	Aggregated Content Error on Channel B —This flag is set when a content error was detected on channel B. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
ASEB	Aggregated Syntax Error on Channel B —This flag is set when a syntax error was detected on channel B. Syntax errors are detected in the communication slots, the symbol window, and the NIT. 0 No syntax error detected 1 Syntax errors detected
AVFB	Aggregated Valid Frame on Channel B —This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel B. 0 No syntactically valid frames received 1 At least one syntactically valid frame received
WUA	Wakeup Symbol Received on Channel A —This flag is set when a wakeup symbol was received on channel A. 0 No wakeup symbol received 1 Wakeup symbol received

Table 997. FR_PSR3 field descriptions (continued)

Field	Description
ABVA	Aggregated Boundary Violation on Channel A —This flag is set when a boundary violation was detected on channel A. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
AACA	Aggregated Additional Communication on Channel A —This flag is set when a valid frame was received in a slot on channel A that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
ACEA	Aggregated Content Error on Channel A —This flag is set when a content error has been detected on channel A. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
ASEA	Aggregated Syntax Error on Channel A —This flag is set when a syntax error has been detected on channel A. Syntax errors are detected in the communication slots, the symbol window, and the NIT. 0 No syntax error detected 1 Syntax errors detected
AVFA	Aggregated Valid Frame on Channel A —This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel A. 0 No syntactically valid frames received 1 At least one syntactically valid frame received

51.5.2.25 MacroTICK Counter Register (FR_MTCTR)

Figure 963. MacroTICK Counter Register (FR_MTCTR)

Base + 0x0030

This register provides the macroTICK count of the current communication cycle.

Table 998. FR_MTCTR field descriptions

Field	Description
MTCT	MacroTICK Counter —protocol-related variable: vMacroTICK . This field provides the macroTICK count of the current communication cycle.

51.5.2.26 Cycle Counter Register (FR_CYCTR)

Figure 964. Cycle Counter Register (FR_CYCTR)

This register provides the number of the current communication cycle.

Table 999. FR_CYCTR field descriptions

Field	Description
CYCCNT	Cycle Counter —protocol-related variable: vCycleCounter . This field provides the number of the current communication cycle. If the counter reaches the maximum value of 63, the counter wraps and starts from 0 again.

51.5.2.27 Slot Counter Channel A Register (FR_SLTCTAR)

Figure 965. Slot Counter Channel A Register (FR_SLTCTAR)

This register provides the number of the current slot in the current communication cycle for channel A.

Table 1000. FR_SLTCTAR field descriptions

Field	Description
SLOTCNTA	Slot Counter Value for Channel A —protocol-related variable: vSlotCounter for channel A. This field provides the number of the current slot in the current communication cycle.

51.5.2.28 Slot Counter Channel B Register (FR_SLTCTBR)

Figure 966. Slot Counter Channel B Register (FR_SLTCTBR)

Base + 0x0036

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	SLOTCNTB										
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the number of the current slot in the current communication cycle for channel B.

Table 1001. FR_SLTCTBR field descriptions

Field	Description
SLOTCNTA	Slot Counter Value for Channel B —protocol-related variable: <i>vSlotCounter</i> for channel B. This field provides the number of the current slot in the current communication cycle.

51.5.2.29 Rate Correction Value Register (FR_RTCORVR)

Figure 967. Rate Correction Value Register (FR_RTCORVR)

Base + 0x0038

Additional Reset: RUN Command

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RATECORR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Table 1002. FR_RTCORVR Field Descriptions

Field	Description
RATECORR	Rate Correction Value —protocol-related variable: <i>vRateCorrection</i> (before value limitation and external rate correction). This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by <i>rate_correction_out</i> in the Protocol Configuration Register 13 (FR_PCR13) , the clock correction reached limit interrupt flag (CCL_IF) is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0) . <i>Note: If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.</i>

51.5.2.30 Offset Correction Value Register (FR_OFCORVR)

Figure 968. Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Table 1003. FR_OFCORVR Field Descriptions

Field	Description
OFFSET-CORR	Offset Correction Value —protocol-related variable: <i>vOffsetCorrection</i> (before value limitation and external offset correction). This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by <code>offset_correction_out</code> field in the Protocol Configuration Register 29 (FR_PCR29) , the clock correction reached limit interrupt flag <code>CCL_IF</code> is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0) . <i>Note: If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.</i>

51.5.2.31 Combined Interrupt Flag Register (FR_CIFR)

Figure 969. Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in [Figure 1100](#). The individual interrupt flags `WUPIF`, `FAFBIF`, and `FAFAIF` are copies of corresponding flags in the [Global Interrupt Flag and Enable Register \(FR_GIFER\)](#) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the [Global Interrupt Flag and Enable Register \(FR_GIFER\)](#).

Note: The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the [Global Interrupt Flag and Enable Register \(FR_GIFER\)](#).

Table 1004. FR_CIFR field descriptions

Field	Description
MIF	Module Interrupt Flag —This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
PRIF	Protocol Interrupt Flag —This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
CHIF	CHI Interrupt Flag —This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1. 0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
WUPIF	Wakeup Interrupt Flag —Provides the same value as FR_GIFER[WUPIF].
FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag —Provides the same value as FR_GIFER[FAFBIF].
FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag —Provides the same value as FR_GIFER[FAFAIF].
RBIF	Receive Message Buffer Interrupt Flag —This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted 1 At least one individual receive message buffers has the MBIF flag asserted
TBIF	Transmit Message Buffer Interrupt Flag —This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted 1 At least one individual transmit message buffers has the MBIF flag asserted

51.5.2.32 System Memory Access Timeout Register (FR_SYMATOR)

Figure 970. System Memory Access Time-Out Register (FR_SYMATOR)

Base + 0x003E								Write: Disabled mode								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	TIMEOUT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Table 1005. FR_SYMATOR field descriptions

Field	Description
TIMEOUT	System Memory Access Timeout —This value defines when a system bus access timeout is detected. For a detailed description see Section 51.7.1.1: Configure System Memory Access Timeout Register (FR_SYMATOR) and Section 51.6.19.1.2: System bus access timeout .

51.5.2.33 Sync Frame Counter Register (FR_SFCNTR)

Figure 971. Sync Frame Counter Register (FR_SFCNTR)

Base + 0x0040				Additional Reset: RUN Command												
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SFEVB				SFEVA				SFODB				SFODA			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 macroticks after offset correction start.

Note: *If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.*
If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the SFODB and SFODA values.

Table 1006. FR_SFCNTR Field Descriptions

Field	Description
SFEVB	Sync Frames Channel B, even cycle—protocol-related variable: size of (vsSyncIdListB for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
SFEVA	Sync Frames Channel A, even cycle—protocol related variable: size of (vsSyncIdListA for even cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
SFODB	Sync Frames Channel B, odd cycle—protocol-related variable: size of (vsSyncIdListB for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
SFODA	Sync Frames Channel A, odd cycle—protocol-related variable: size of (vsSyncIdListA for odd cycle). This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.

51.5.2.34 Sync Frame Table Offset Register (FR_SFTOR)

Figure 972. Sync Frame Table Offset Register (FR_SFTOR)

Base + 0x0042

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SFT_OFFSET[15:1]															0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the FlexRay memory area related offset for sync frame tables. For more details, see [Section 51.6.12, “Sync frame ID and sync frame deviation tables”](#).

Table 1007. FR_SFTOR field description

Field	Description
SFT_OFFSET	Sync Frame Table Offset —The offset of the sync frame tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus, STF_OFFSET[0] is always 0.

51.5.2.35 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Figure 973. Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Base + 0x0044

Write: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	CYCNUM						ELKS	OLKS	EVAL	OVAL	0	0	SDV EN	SID EN
W	ELKT	OLKT														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see [Section 51.6.12, “Sync frame ID and sync frame deviation tables”](#).

Table 1008. FR_SFTCCSR field descriptions

Field	Description
ELKT	Even Cycle Tables Lock/Unlock Trigger —This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables
OLKT	Odd Cycle Tables Lock/Unlock Trigger —This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables
CYCNUM	Cycle Number —This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.

Table 1008. FR_SFTCCSR field descriptions

Field	Description
ELKS	Even Cycle Tables Lock Status —This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables 1 Application has locked the even cycle tables
OLKS	Odd Cycle Tables Lock Status —This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables 1 Application has locked the odd cycle tables
EVAL	Even Cycle Tables Valid —This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
OVAL	Odd Cycle Tables Valid —This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent)
OPT	One Pair Trigger —This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.
SDVEN	Sync Frame Deviation Table Enable —This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area <i>Note: If SDVEN is set to 1, then SIDEN must also be set to 1.</i>
SIDEN	Sync Frame ID Table Enable —This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

51.5.2.36 Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Figure 974. Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

This register defines the Sync Frame Rejection Filter ID. The application must update this register outside of the static segment. If the application updates this register in the static segment, it can appear that the CC accepts the sync frame in the current cycle.

Table 1009. FR_SFIDRFR field descriptions

Field	Description
SYNFRID	Sync Frame Rejection ID —This field defines the frame ID of a frame that must not be used for clock synchronization. For details see Section 51.6.15.2, “Sync Frame Rejection Filtering .

51.5.2.37 Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR)

Figure 975. Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR)

This register defines the sync frame acceptance filter value. For details on filtering, see [Section 51.6.15, “Sync frame filtering](#).

Table 1010. FR_SFIDAFVR Field Descriptions

Field	Description
FVAL	Filter Value —This field defines the value for the sync frame acceptance filtering.

51.5.2.38 Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR)

Figure 976. Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR)

This register defines the sync frame acceptance filter mask. For details on filtering see [Section 51.6.15.1, “Sync frame acceptance filtering”](#).

Table 1011. FR_SFIDAFMR Field Descriptions

Field	Description
FMSK	Filter Mask —This field defines the mask for the sync frame acceptance filtering.

51.5.2.39 Network Management Vector Registers (FR_NMVR0–FR_NMVR5)

Figure 977. Network Management Vector Registers (FR_NMVR0–FR_NMVR5)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the [Network Management Vector Length Register \(FR_NMVLR\)](#). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the [Network Management Vector Registers \(FR_NMVR0–FR_NMVR5\)](#), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Table 1012. NMVR[0:5] field descriptions

Field	Description
NMVP	Network Management Vector Part —The mapping between the <i>Network Management Vector Registers</i> (<i>FR_NMVR0–FR_NMVR5</i>) and the receive message buffer payload bytes in NMV[0:11] is depicted in <i>Table 1013</i> .

Table 1013. Mapping of NMVRn to the Received Payload Bytes NMVn

NMVRn Register	NMVn Received Payload
FR_NMVR0[NMVP[15:8]]	NMV0
FR_NMVR0[NMVP[7:0]]	NMV1
FR_NMVR1[NMVP[15:8]]	NMV2
FR_NMVR1[NMVP[7:0]]	NMV3
...	
FR_NMVR5[NMVP[15:8]]	NMV10
FR_NMVR5[NMVP[7:0]]	NMV11

51.5.2.40 Network Management Vector Length Register (FR_NMVLRL)

Figure 978. Network Management Vector Length Register (FR_NMVLRL)

Base + 0x0058

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	NMVL			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the length of the network management vector in bytes.

Table 1014. FR_NMVLRL field descriptions

Field	Description
NMVL	Network Management Vector Length —protocol-related variable: <i>gNetworkManagementVectorLength</i> . This field defines the length of the Network Management Vector in bytes. Legal values are between 0 and 12.

51.5.2.41 Timer Configuration and Control Register (FR_TICCR)

Figure 979. Timer Configuration and Control Register (FR_TICCR)

Base + 0x005A

Write: T2_CFG: *POC:config*
T2_REP, T1_REP, T1SP, T2SP, T1TR, T2TR: Normal mode

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	T2_CFG	T2_REP	0	0	0	T2ST	0	0	0	T1_REP	0	0	0	T1ST
W						T2SP	T2TR							T1SP	T1TR	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to configure and control the T1 and T2 timers. For timer details, see [Section 51.6.17, “Timer support”](#). The T1 timer is an absolute timer. The T2 timer can be configured as an absolute or relative timer.

Table 1015. FR_TICCR field descriptions

Field	Description
T2_CFG	Timer T2 Configuration —This bit configures the timebase mode of timer T2. 0 T2 is absolute timer. 1 T2 is relative timer.
T2_REP	Timer T2 Repetitive Mode —This bit configures the repetition mode of timer T2. 0 T2 is non repetitive 1 T2 is repetitive
T2SP	Timer T2 Stop —This trigger bit is used to stop timer T2. 0 No effect 1 Stop timer T2
T2TR	Timer T2 Trigger —This trigger bit is used to start timer T2. 0 No effect 1 Start timer T2
T2ST	Timer T2 State —This status bit provides the current state of timer T2. 0 Timer T2 is idle 1 Timer T2 is running
T1_REP	Timer T1 Repetitive Mode —This bit configures the repetition mode of timer T1. 0 T1 is non repetitive 1 T1 is repetitive
T1SP	Timer T1 Stop —This trigger bit is used to stop timer T1. 0 No effect 1 Stop timer T1
T1TR	Timer T1 Trigger —This trigger bit is used to start timer T1. 0 No effect 1 Start timer T1
T1ST	Timer T1 State —This status bit provides the current state of timer T1. 0 Timer T1 is idle 1 Timer T1 is running

Note: Both timers are deactivated immediately when the protocol enters a state different from *POC:normal active* or *POC:normal passive*.

51.5.2.42 Timer 1 Cycle Set Register (FR_TI1CYSR)

Figure 980. Timer 1 Cycle Set Register (FR_TI1CYSR)

This register defines the cycle filter value and the cycle filter mask for timer T1. For a detailed description of timer T1, refer to [Section 51.6.17.1, “Absolute timer T1”](#).

Table 1016. FR_TI1CYSR Field Descriptions

Field	Description
T1_CYC_VAL	Timer T1 Cycle Filter Value —This field defines the cycle filter value for timer T1.
T1_CYC_MSK	Timer T1 Cycle Filter Mask —This field defines the cycle filter mask for timer T1.

Note: If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

51.5.2.43 Timer 1 Macrotick Offset Register (FR_TI1MTOR)

Figure 981. Timer 1 Macrotick Offset Register (FR_TI1MTOR)

This register holds the macrotick offset value for timer T1. For a detailed description of timer T1, refer to [Section 51.6.17.1, “Absolute timer T1”](#).

Table 1017. FR_TI1MTOR Field Descriptions

Field	Description
T1_MTOFFSET	Timer 1 Macrotick Offset —This field defines the macrotick offset value for timer 1.

Note: If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

51.5.2.44 Timer 2 Configuration Register 0 (FR_TI2CR0)

Figure 982. Timer 2 Configuration Register 0 (FR_TI2CR0)

The content of this register depends on the value of the T2_CFG bit in the [Timer Configuration and Control Register \(FR_TICCR\)](#). For a detailed description of timer T2, refer to [Section 51.6.17.2, "Absolute/relative timer T2"](#).

Table 1018. FR_TI2CR0 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
T2_CYC_VAL	Timer T2 Cycle Filter Value —This field defines the cycle filter value for timer T2.
T2_CYC_MSK	Timer T2 Cycle Filter Mask —This field defines the cycle filter mask for timer T2.
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
T2_MTCNT[31:16]	Timer T2 Macrotick High Word —This field defines the high word of the macrotick count for timer T2.

Note: *If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and timer T2 will expire according to the changed values.*

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

51.5.2.45 Timer 2 Configuration Register 1 (FR_TI2CR1)

Figure 983. Timer 2 Configuration Register 1 (FR_TI2CR1)

The content of this register depends on the value of the T2_CFG bit in the [Timer Configuration and Control Register \(FR_TICCR\)](#). For a detailed description of timer T2, refer to [Section 51.6.17.2, “Absolute/relative timer T2](#).

Table 1019. FR_TI2CR1 field descriptions

Field	Description
Fields for absolute timer T2 (FR_TICCR[T2_CFG] = 0)	
T2_MTOFFSET	Timer T2 Macrotick Offset —This field holds the macrotick offset value for timer T2.
Fields for relative timer T2 (FR_TICCR[T2_CFG] = 1)	
T2_MTCNT[15:0]	Timer T2 Macrotick Low Word —This field defines the low word of the macrotick value for timer T2.

Note: *If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.*

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

51.5.2.46 Slot Status Selection Register (FR_SSSR)

Figure 984. Slot Status Selection Register (FR_SSSR)

Base + 0x0064				16-bit write access required								Write: Anytime				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	SEL		0	SLOTNUMBER										
W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to access the four internal non-memory-mapped Slot Status Selection Registers FR_SSSR0 to FR_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding [Slot Status Registers \(FR_SSR0–FR_SSR7\)](#) according to [Table 1021](#). For a detailed description of slot status monitoring, refer to [Section 51.6.18, “Slot status monitoring](#).

Table 1020. FR_SSSR field descriptions

Field	Description
WMD	Write Mode —This control bit defines the write mode of this register. 0 Write to all fields in this register on write access 1 Write to SEL field only on write access

Table 1020. FR_SSSR field descriptions

Field	Description
SEL	Selector —This field selects one of the four internal slot status selection registers for access. 00 Select FR_SSSR0 01 Select FR_SSSR1 10 Select FR_SSSR2 11 Select FR_SSSR3
SLOTNUMBER	Slot Number —This field specifies the number of the slot whose status will be saved in the corresponding slot status registers. <i>Note: If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start.</i>

Table 1021. Mapping between FR_SSSRn and FR_SSRn

Internal Slot Status Selection Register	Write the Slot Status of the Slot Selected by FR_SSSRn for each			
	Even Communication Cycle		Odd Communication Cycle	
	For Channel B to	For Channel A to	For Channel B to	For Channel A to
FR_SSSR0	FR_SSR0[15:8]	FR_SSR0[7:0]	FR_SSR1[15:8]	FR_SSR1[7:0]
FR_SSSR1	FR_SSR2[15:8]	FR_SSR2[7:0]	FR_SSR3[15:8]	FR_SSR3[7:0]
FR_SSSR2	FR_SSR4[15:8]	FR_SSR4[7:0]	FR_SSR5[15:8]	FR_SSR5[7:0]
FR_SSSR3	FR_SSR6[15:8]	FR_SSR6[7:0]	FR_SSR7[15:8]	FR_SSR7[7:0]

51.5.2.47 Slot Status Counter Condition Register (FR_SSCCR)

Figure 985. Slot Status Counter Condition Register (FR_SSCCR)

Base + 0x0066				16-bit write access required								Write: Anytime				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	SEL		0	CNTCFG		MCY	VFR	SYF	NUF	SUF	STATUSMASK[3:0]			
W	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to access and program the four internal non-memory-mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal Slot Status Counter Condition Registers defines the mode and the conditions for incrementing the counter in the corresponding [Slot Status Counter Registers \(FR_SSCR0–FR_SSCR3\)](#). The correspondence is given in [Table 1023](#). For a detailed description of slot status counters, refer to [Section 51.6.18.4, “Slot Status Counter Registers](#).

Table 1022. FR_SSCCR field descriptions

Field	Description
WMD	Write Mode —This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
SEL	Selector —This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0 01 select FR_SSCCR1 10 select FR_SSCCR2 11 select FR_SSCCR3
CNTCFG	Counter Configuration —These bit field controls the channel related incrementing of the slot status counter. 00 Increment by 1 if condition is fulfilled on channel A. 01 Increment by 1 if condition is fulfilled on channel B. 10 Increment by 1 if condition is fulfilled on at least one channel. 11 Increment by 2 if condition is fulfilled on both channels channel. Increment by 1 if condition is fulfilled on only one channel.
MCY	Multi Cycle Selection —This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only 1 The Slot Status Counter accumulates over multiple communication cycles
VFR	Valid Frame Restriction —This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only 1 The counter is restricted to valid frames only
SYF	Sync Frame Restriction —This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit 1 The counter is restricted to frames with the sync frame indicator bit set to 1
NUF	Null Frame Restriction —This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit 1 The counter is restricted to frames with the null frame indicator bit set to 0
SUF	Startup Frame Restriction —This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit 1 The counter is restricted to received frames with the startup frame indicator bit set to 1
STATUS MASK[3:0]	Slot Status Mask —This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3] —This bit enables the counting for slots with the syntax error indicator bit set to 1 STATUSMASK[2] —This bit enables the counting for slots with the content error indicator bit set to 1 STATUSMASK[1] —This bit enables the counting for slots with the boundary violation indicator bit set to 1 STATUSMASK[0] —This bit enables the counting for slots with the transmission conflict indicator bit set to 1

Table 1023. Mapping between internal FR_SSCCRn and FR_SSCRn

Condition Register	Condition Defined for Register
FR_SSCCR0	FR_SSCR0
FR_SSCCR1	FR_SSCR1
FR_SSCCR2	FR_SSCR2
FR_SSCCR3	FR_SSCR3

51.5.2.48 Slot Status Registers (FR_SSR0–FR_SSR7)

Figure 986. Slot Status Registers (FR_SSR0–FR_SSR7)

Base + 0x0068 (FR_SSR0)

Base + 0x006A (FR_SSR1)

Base + 0x006C (FR_SSR2)

Base + 0x006E (FR_SSR3)

Base + 0x0070 (FR_SSR4)

Base + 0x0072 (FR_SSR5)

Base + 0x0074 (FR_SSR6)

Base + 0x0076 (FR_SSR7)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	VFB	SYB	NFB	SUB	SEB	CEB	BVB	TCB	VFA	SYA	NFA	SUA	SEA	CEA	BVA	TCA
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each of these eight registers holds the status vector of the slot specified in the corresponding internal Slot Status Selection Register, which can be programmed using the [Slot Status Selection Register \(FR_SSSR\)](#). Each register is updated after the end of the corresponding slot as shown in [Figure 1096](#). The register bits are directly related to the protocol variables and described in more detail in [Section 51.6.18, “Slot status monitoring”](#).

Table 1024. FR_SSR0–FR_SSR7 field descriptions

Field	Description
VFB	Valid Frame on Channel B —protocol-related variable: vSS!ValidFrame channel B. 0 vSS!ValidFrame = 0 1 vSS!ValidFrame = 1
SYB	Sync Frame Indicator Channel B —protocol-related variable: vRF!Header!SyFIndicator channel B. 0 vRF!Header!SyFIndicator = 0 1 vRF!Header!SyFIndicator = 1
NFB	Null Frame Indicator Channel B —protocol-related variable: vRF!Header!NFIndicator channel B. 0 vRF!Header!NFIndicator = 0 1 vRF!Header!NFIndicator = 1

Table 1024. FR_SSR0–FR_SSR7 field descriptions

Field	Description
SUB	Startup Frame Indicator Channel B —protocol-related variable: <i>vRF!Header!SuFIndicator</i> channel B. 0 <i>vRF!Header!SuFIndicator</i> = 0 1 <i>vRF!Header!SuFIndicator</i> = 1
SEB	Syntax Error on Channel B —protocol-related variable: <i>vSS!SyntaxError</i> channel B. 0 <i>vSS!SyntaxError</i> = 0 1 <i>vSS!SyntaxError</i> = 1
CEB	Content Error on Channel B —protocol-related variable: <i>vSS!ContentError</i> channel B. 0 <i>vSS!ContentError</i> = 0 1 <i>vSS!ContentError</i> = 1
BVB	Boundary Violation on Channel B —protocol-related variable: <i>vSS!BViolation</i> channel B. 0 <i>vSS!BViolation</i> = 0 1 <i>vSS!BViolation</i> = 1
TCB	Transmission Conflict on Channel B —protocol-related variable: <i>vSS!TxConflict</i> channel B. 0 <i>vSS!TxConflict</i> = 0 1 <i>vSS!TxConflict</i> = 1
VFA	Valid Frame on Channel A —protocol-related variable: <i>vSS!ValidFrame</i> channel A. 0 <i>vSS!ValidFrame</i> = 0 1 <i>vSS!ValidFrame</i> = 1
SYA	Sync Frame Indicator Channel A —protocol-related variable: <i>vRF!Header!SyFIndicator</i> channel A. 0 <i>vRF!Header!SyFIndicator</i> = 0 1 <i>vRF!Header!SyFIndicator</i> = 1
NFA	Null Frame Indicator Channel A —protocol-related variable: <i>vRF!Header!NFIndicator</i> channel A. 0 <i>vRF!Header!NFIndicator</i> = 0 1 <i>vRF!Header!NFIndicator</i> = 1
SUA	Startup Frame Indicator Channel A —protocol-related variable: <i>vRF!Header!SuFIndicator</i> channel A. 0 <i>vRF!Header!SuFIndicator</i> = 0 1 <i>vRF!Header!SuFIndicator</i> = 1
SEA	Syntax Error on Channel A —protocol-related variable: <i>vSS!SyntaxError</i> channel A. 0 <i>vSS!SyntaxError</i> = 0 1 <i>vSS!SyntaxError</i> = 1
CEA	Content Error on Channel A —protocol-related variable: <i>vSS!ContentError</i> channel A. 0 <i>vSS!ContentError</i> = 0 1 <i>vSS!ContentError</i> = 1
BVA	Boundary Violation on Channel A —protocol-related variable: <i>vSS!BViolation</i> channel A. 0 <i>vSS!BViolation</i> = 0 1 <i>vSS!BViolation</i> = 1
TCA	Transmission Conflict on Channel A —protocol-related variable: <i>vSS!TxConflict</i> channel A. 0 <i>vSS!TxConflict</i> = 0 1 <i>vSS!TxConflict</i> = 1

51.5.2.49 Slot Status Counter Registers (FR_SSCR0–FR_SSCR3)

Figure 987. Slot Status Counter Registers (FR_SSCR0–FR_SSCR3)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal Slot Status Counter Condition Register (FR_SSCCRn), which can be programmed by using the [Slot Status Counter Condition Register \(FR_SSCCR\)](#). For more details, see [Section 51.6.18.4, “Slot Status Counter Registers”](#).

Note: If the counter has reached its maximum value 0xFFFF and is in Multicycle mode (that is, FR_SSCCRn[MCY] = 1), the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be put into Multicycle mode again.

Table 1025. FR_SSCR0–FR_SSCR3 field descriptions

Field	Description
SLOTSTATUSCNT	Slot Status Counter —This field provides the current value of the Slot Status Counter.

51.5.2.50 MTS A Configuration Register (FR_MTSACFR)

Figure 988. MTS A Configuration Register (FR_MTSACFR)

This register controls the transmission of the Media Access Test Symbol (MTS) on channel A. For more details, see [Section 51.6.13, “MTS generation”](#).

Table 1026. FR_MTSACFR field descriptions

Field	Description
MTE	Media Access Test Symbol Transmission Enable —This control bit is used to enable and disable the transmission of the MTS in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
CYCCNTMSK	Cycle Counter Mask—This field provides the filter mask for the MTS cycle count filter.
CYCCNTVAL	Cycle Counter Value —This field provides the filter value for the MTS cycle count filter.

51.5.2.51 MTS B Configuration Register (FR_MTSBCFR)

Figure 989. MTS B Configuration Register (FR_MTSBCFR)

This register controls the transmission of the Media Access Test Symbol (MTS) on channel B. For more details, see [Section 51.6.13, “MTS generation”](#).

Table 1027. FR_MTSBCFR field descriptions

Field	Description
MTE	Media Access Test Symbol Transmission Enable —This control bit is used to enable and disable the transmission of the MTS in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
CYCCNTMSK	Cycle Counter Mask—This field provides the filter mask for the MTS cycle count filter.
CYCCNTVAL	Cycle Counter Value —This field provides the filter value for the MTS cycle count filter.

51.5.2.52 Receive Shadow Buffer Index Register (FR_RSBIR)

Figure 990. Receive Shadow Buffer Index Register (FR_RSBIR)

This register is used to provide and retrieve the indices of the message buffer header fields currently associated with the receive shadow buffers. For more details on the receive shadow buffer concept, refer to [Section 51.6.6.3.5, “Receive shadow buffer concept”](#).

Table 1028. FR_RSBIR field descriptions

Field	Description
WMD	Write Mode —This bit controls the write mode for this register. 0 Update SEL and RSBIDX field on register write 1 Update only SEL field on register write
SEL	Selector —This field is used to select the internal receive shadow buffer index register for access. 00 FR_RSBIR_A1—receive shadow buffer index register for channel A, segment 1 01 FR_RSBIR_A2—receive shadow buffer index register for channel A, segment 2 10 FR_RSBIR_B1—receive shadow buffer index register for channel B, segment 1 11 FR_RSBIR_B2—receive shadow buffer index register for channel B, segment 2
RSBIDX _{A1} RSBIDX _{A2} RSBIDX _{B1} RSBIDX _{B2}	Receive Shadow Buffer Index —This field contains the current index of the message buffer header field of the receive shadow message buffer selected by the SEL field. The CC uses this index to determine the physical location of the shadow buffer header field in the FlexRay memory area. The CC will update this field during receive operation. The application provides initial message buffer header index value in the configuration phase. CC: Updates the message buffer header index after successful reception. Application: Provides initial message buffer header index. Legal Values are $0 \leq i \leq 131$. Illegal values will be detected during the message buffer search.

51.5.2.53 Receive FIFO Start Data Offset Register (FR_RFSDOR)

Figure 991. Receive FIFO Start Data Offset Register (FR_RFSDOR)

Table 1029. FR_RFSDOR field descriptions

Field	Description
SDO _A SDO _B	Start Data Field Offset —This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO's first message buffer header field. For configuration constraints, see Section 51.7.1.2, “Configure data field offsets” .

Note: Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses, the content of the FR_RFSDOR register corresponds to the start address of the payload area of the selected FIFO.

51.5.2.54 Receive FIFO System Memory Base Address Register (FR_RFSYMBADR)

Figure 992. Receive FIFO System Memory Base Address High Register (FR_RFSYMBADHR)

Figure 993. Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Table 1030. FR_RFSYMBADR field descriptions

Field	Description
SMBA	System Memory Base Address —This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defined as a byte address.

51.5.2.55 Receive FIFO Periodic Timer Register (FR_RFPTR)

Figure 994. Receive FIFO Periodic Timer Register (FR_RFPTR)

This register holds the periodic timer duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (see [Section 51.6.9.3, "FIFO periodic timer"](#)).

Table 1031. FR_RFPTR field descriptions

Field	Description
PTD	Periodic Timer Duration —This value defines the periodic timer duration in terms of macroticks. 0000 Timer stays expired 3FFF Timer never expires other Timer expires after specified number of macroticks, expires and is restarted at each cycle start

51.5.2.56 Receive FIFO Watermark and Selection Register (FR_RFWMSR)

Figure 995. Receive FIFO Watermark and Selection Register (FR_RFWMSR)

This register is used to:

- Select a receiver FIFO for subsequent programming access through the receiver FIFO configuration registers summarized in [Table 1032](#).
- Define the watermark for the selected FIFO.

Table 1032. SEL-controlled receiver FIFO registers

Register
Receive FIFO Start Index Register (FR_RFSIR)
Receive FIFO Depth and Size Register (FR_RFDSR)
Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)
Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Table 1033. FR_RFWMSR field descriptions

Field	Description
WM _A WM _B	Watermark —This field defines the watermark value for the selected FIFO. This value is used to control the generation of the almost full interrupt flags.
SEL	Select —This control bit selects the receiver FIFO for subsequent programming. 0 Receiver FIFO for channel A selected 1 Receiver FIFO for channel B selected

51.5.2.57 Receive FIFO Start Index Register (FR_RFSIR)

Figure 996. Receive FIFO Start Index Register (FR_RFSIR)

Base + 0x0088

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	SIDX _A /SIDX _B									
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the message buffer header index of the first message buffer of the selected FIFO.

Table 1034. FR_RFSIR field descriptions

Field	Description
SIDX _A SIDX _B	Start Index —This field defines the number of the message buffer header field of the selected FIFO's first message buffer. The CC uses the value of the SIDX field to determine the physical location of the receiver FIFO's first message buffer header field.

51.5.2.58 Receive FIFO Depth and Size Register (FR_RFDSR)

Figure 997. Receive FIFO Depth and Size Register (FR_RFDSR)

Base + 0x008A

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FIFO_DEPTH _A /FIFO_DEPTH _B								0	ENTRY_SIZE _A /ENTRY_SIZE _B						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the structure of the selected FIFO, i.e. the number of entries and the size of each entry.

Table 1035. RFDSR Field Descriptions

Field	Description
FIFO_DEPTH _A FIFO_DEPTH _B	FIFO Depth —This field defines the depth (the number of entries) of the selected FIFO. Note: If the FIFO_DEPTH is configured to 0, FR_RFFIDRFMR[FIDRFMSK] must be configured to 0 as well to ensure that no frames are received into the FIFO.
ENTRY_SIZE _A ENTRY_SIZE _B	Entry Size —This field defines the size of the frame data sections for the selected FIFO in two-byte entities.

51.5.2.59 Receive FIFO A Read Index Register (FR_RFARIR)

Figure 998. Receive FIFO A Read Index Register (FR_RFARIR)

This register provides the message buffer header index of the next available FIFO A entry that the application can read.

Table 1036. FR_RFARIR field descriptions

Field	Description
RDIDX	Read Index —This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

Note: If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

51.5.2.60 Receive FIFO B Read Index Register (FR_RFBRIR)

Figure 999. Receive FIFO B Read Index Register (FR_RFBRIR)

This register provides the message buffer header index of the next available FIFO B entry that the application can read.

Table 1037. FR_RFBRIR field descriptions

Field	Description
RDIDX	Read Index —This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

Note: If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

51.5.2.61 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

Figure 1000. Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

Base + 0x00EE

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	FLB								FLA							
W	PCB								PCA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs.

Table 1038. FR_RFFLPCR field descriptions

Field	Description
FLB	Fill Level FIFO B —This field provides the current number of entries in the FIFO B.
FLA	Fill Level FIFO A —This field provides the current number of entries in the FIFO A.
PCB	Pop Count FIFO B —This field defines the number of entries to be removed from FIFO B.
PCA	Pop Count FIFO A —This field defines the number of entries to be removed from FIFO A.

Note: If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, then the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

51.5.2.62 Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

Figure 1001. Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

Base + 0x0090

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MIDAFVAL _A /MIDAFVAL _B															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the filter value for the message ID acceptance filter of the selected FIFO. For details on message ID filtering, see [Section 51.6.9.9, “FIFO filtering”](#).

Table 1039. FR_RFMIDAFVR field descriptions

Field	Description
MIDAFVAL _A MIDAFVAL _B	Message ID Acceptance Filter Value —Filter value for the message ID acceptance filter.

51.5.2.63 Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)

Figure 1002. Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)

This register defines the filter mask for the message ID acceptance filter of the selected FIFO. For details on message ID filtering, see [Section 51.6.9.9, "FIFO filtering"](#).

Table 1040. FR_RFMIDAFMR field descriptions

Field	Description
MIDAFMSK _A MIDAFMSK _B	Message ID Acceptance Filter Mask —Filter mask for the message ID acceptance filter.

51.5.2.64 Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)

Figure 1003. Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)

This register defines the filter value for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering, see [Section 51.6.9.9, "FIFO filtering"](#).

Table 1041. FR_RFFIDRFVR field descriptions

Field	Description
FIDRFVAL _A FIDRFVAL _B	Frame ID Rejection Filter Value —Filter value for the frame ID rejection filter.

51.5.2.65 Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)

Figure 1004. Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)

Base + 0x0096

Write: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	FIDRFMSK _A /FIDRFMSK _B										
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the filter mask for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see [Section 51.6.9.9, "FIFO filtering"](#).

Table 1042. FR_RFFIDRFMR field descriptions

Field	Description
FIDRFMSK	Frame ID Rejection Filter Mask—Filter mask for the frame ID rejection filter.

51.5.2.66 Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Figure 1005. Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Base + 0x0098

16-bit write access required

Write: WMD, IBD, SEL: Any Time
SID: *POC:config*

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0				0	SID _A /SID _B										
W	WMD	IBD	SEL													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides access to the four internal frame ID range filter boundary registers of the selected FIFO. For details on frame ID range filter, see [Section 51.6.9.9, "FIFO filtering"](#).

Table 1043. FR_RFRFCFR field descriptions

Field	Description
WMD	Write Mode —This control bit defines the write mode of this register. 0 Write to all fields in this register on write access 1 Write to SEL and IBD field only on write access
IBD	Interval Boundary —This control bit selects the interval boundary to be programmed with the SID value. 0 Program lower interval boundary 1 Program upper interval boundary

Table 1043. FR_RFRFCFR field descriptions

Field	Description
SEL	Filter Selector —This control field selects the frame ID range filter to be accessed. 00 Select frame ID range filter 0 01 Select frame ID range filter 1 10 Select frame ID range filter 2 11 Select frame ID range filter 3
SID _A SID _B	Slot ID —Defines the IBD-selected frame ID boundary value for the SEL-selected range filter.

51.5.2.67 Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Figure 1006. Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Base + 0x009A

Write: Anytime

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	F3M	F2M	F1M	F0M	0	0	0	0	F3EN	F2EN	F1EN	F0EN
W					D	D	D	D								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to enable and disable each frame ID range filter and to define whether it is running as an acceptance or rejection filter.

Table 1044. FR_RFRFCTR field descriptions

Field	Description
F3MD	Range Filter 3 Mode —This control bit defines the filter mode of the frame ID range filter 3. 0 Range filter 3 runs as acceptance filter 1 Range filter 3 runs as rejection filter
F2MD	Range Filter 2 Mode —This control bit defines the filter mode of the frame ID range filter 2. 0 Range filter 2 runs as acceptance filter 1 Range filter 2 runs as rejection filter
F1MD	Range Filter 1 Mode —This control bit defines the filter mode of the frame ID range filter 1. 0 Range filter 1 runs as acceptance filter 1 Range filter 1 runs as rejection filter
F0MD	Range Filter 0 Mode —This control bit defines the filter mode of the frame ID range filter 0. 0 Range filter 0 runs as acceptance filter 1 Range filter 0 runs as rejection filter
F3EN	Range Filter 3 Enable —This control bit is used to enable and disable the frame ID range filter 3. 0 Range filter 3 disabled 1 Range filter 3 enabled
F2EN	Range Filter 2 Enable —This control bit is used to enable and disable the frame ID range filter 2. 0 Range filter 2 disabled 1 Range filter 2 enabled

Table 1044. FR_RFRFCTR field descriptions (continued)

Field	Description
F1EN	Range Filter 1 Enable —This control bit is used to enable and disable the frame ID range filter 1. 0 Range filter 1 disabled 1 Range filter 1 enabled
F0EN	Range Filter 0 Enable —This control bit is used to enable and disable the frame ID range filter 0. 0 Range filter 0 disabled 1 Range filter 0 enabled

51.5.2.68 Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)

Figure 1007. Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)

Base + 0x009C

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	LASTDYNTXSLOTA										
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the number of the last transmission slot in the dynamic segment for channel A. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Table 1045. FR_LDTXSLAR field descriptions

Field	Description
LASTDYNTXSLOTA	Last Dynamic Transmission Slot Channel A —protocol-related variable: zLastDynTxSlot channel A. Number of the last transmission slot in the dynamic segment for channel A. If no frame was transmitted during the dynamic segment on channel A, the value of this field is set to 0.

51.5.2.69 Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

Figure 1008. Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

Base + 0x009E

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	LASTDYNTXSLOTB										
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the number of the last transmission slot in the dynamic segment for channel B. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Table 1046. FR_LDTXSLBR field descriptions

Field	Description
LASTDYNTX SLOTB	Last Dynamic Transmission Slot Channel B —protocol-related variable: zLastDynTxSlot channel B. Number of the last transmission slot in the dynamic segment for channel B. If no frame was transmitted during the dynamic segment on channel B the value of this field is set to 0.

51.5.2.70 Protocol Configuration Registers

The following configuration registers provide the necessary configuration information to the protocol engine. The individual values in the registers are described in [Table 1047](#). For more details about the FlexRay related configuration parameters and the allowed parameter ranges, see *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

Table 1047. Protocol Configuration Register fields

Name	Description ⁽¹⁾	Min	Max	Unit	FR_PCR
coldstart_attempts	gColdstartAttempts			number	3
action_point_offset	gdActionPointOffset - 1			MT	0
cas_rx_low_max	gdCASRxLowMax - 1			gdBit	4
dynamic_slot_idle_phase	gdDynamicSlotIdlePhase			minislot	28
minislot_action_point_offset	gdMinislotActionPointOffset - 1			MT	3
minislot_after_action_point	gdMinislot - gdMinislotActionPointOffset - 1			MT	2
static_slot_length	gdStaticSlot			MT	0
static_slot_after_action_point	gdStaticSlot - gdActionPointOffset - 1			MT	13
symbol_window_exists	gdSymbolWindow !=0	0	1	bool	9
symbol_window_after_action_point	gdSymbolWindow - gdActionPointOffset - 1			MT	6
tss_transmitter	gdTSSTransmitter			gdBit	5
wakeup_symbol_rx_idle	gdWakeupSymbolRxIdle			gdBit	5
wakeup_symbol_rx_low	gdWakeupSymbolRxLow			gdBit	3
wakeup_symbol_rx_window	gdWakeupSymbolRxWindow			gdBit	4
wakeup_symbol_tx_idle	gdWakeupSymbolTxIdle			gdBit	8
wakeup_symbol_tx_low	gdWakeupSymbolTxLow			gdBit	5
noise_listen_timeout	(gListenNoise * pdListenTimeout) - 1			μT	16/17
macro_initial_offset_a	pMacroInitialOffset[A]			MT	6
macro_initial_offset_b	pMacroInitialOffset[B]			MT	16
macro_per_cycle	gMacroPerCycle			MT	10
macro_after_first_static_slot	gMacroPerCycle - gdStaticSlot			MT	1
macro_after_offset_correction	gMacroPerCycle - gOffsetCorrectionStart			MT	28

Table 1047. Protocol Configuration Register fields (continued)

Name	Description ⁽¹⁾	Min	Max	Unit	FR_PCR
max_without_clock_correction_fatal	gMaxWithoutClockCorrectionFatal			cyclepairs	8
max_without_clock_correction_passive	gMaxWithoutClockCorrectionPassive			cyclepairs	8
minislot_exists	gNumberOfMinislots != 0	0	1	bool	9
minislots_max	gNumberOfMinislots - 1			minislot	29
number_of_static_slots	gNumberOfStaticSlots			static slot	2
offset_correction_start	gOffsetCorrectionStart			MT	11
payload_length_static	gPayloadLengthStatic			2 bytes	19
max_payload_length_dynamic	pPayloadLengthDynMax			2 bytes	24
first_minislot_action_point_offset	max(gdActionPointOffset , gdMinislotActionPointOffset) - 1			MT	13
allow_halt_due_to_clock	pAllowHaltDueToClock			bool	26
allow_passive_to_active	pAllowPassiveToActive			cyclepairs	12
cluster_drift_damping	pClusterDriftDamping			μT	24
comp_accepted_startup_range_a	pdAcceptedStartupRange - pDelayCompensation[A]			μT	22
comp_accepted_startup_range_b	pdAcceptedStartupRange - pDelayCompensation[B]			μT	26
listen_timeout	pdListenTimeout - 1			μT	14/15
key_slot_id	pKeySlotId			number	18
key_slot_used_for_startup	pKeySlotUsedForStartup			bool	11
key_slot_used_for_sync	pKeySlotUsedForSync			bool	11
latest_tx	gNumberOfMinislots - pLatestTx			minislot	21
sync_node_max	gSyncNodeMax			number	30
micro_initial_offset_a	pMicroInitialOffset[A]			μT	20
micro_initial_offset_b	pMicroInitialOffset[B]			μT	20
micro_per_cycle	pMicroPerCycle			μT	22/23
micro_per_cycle_min	pMicroPerCycle - pdMaxDrift			μT	24/25
micro_per_cycle_max	pMicroPerCycle + pdMaxDrift			μT	26/27
micro_per_macro_nom_half	round(pMicroPerMacroNom / 2)			μT	7
offset_correction_out	pOffsetCorrectionOut			μT	9
rate_correction_out	pRateCorrectionOut			μT	14
single_slot_enabled	pSingleSlotEnabled			bool	10
wakeup_channel	pWakeupChannel	see Table 1048			10
wakeup_pattern	pWakeupPattern			number	18
decoding_correction_a	pDecodingCorrection + pDelayCompensation[A] + 2			μT	19

Table 1047. Protocol Configuration Register fields (continued)

Name	Description ⁽¹⁾	Min	Max	Unit	FR_PCR
decoding_correction_b	$pDecodingCorrection + pDelayCompensation[B] + 2$			μT	7
key_slot_header_crc	header CRC for key slot	0x000	0x7FF	number	12
extern_offset_correction	pExternOffsetCorrection			μT	29
extern_rate_correction	pExternRateCorrection			μT	21

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the means to control the ECC-related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description, see [Section 51.6.24.2, “Memory error reporting.”](#)

Table 1049. FR_EEIFER field descriptions

Field	Description
Error Overflow Flags	
LRNE_OF	LRAM Non-Corrected Error Overflow Flag—This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected <i>but not corrected</i> on CHI LRAM and interrupt flag LRNE_IF is already 1 b) Memory errors are detected <i>but not corrected</i> on at least two banks of CHI LRAM 0 No such event 1 Non-Corrected Error overflow detected on CHI LRAM
LRCE_OF	LRAM Corrected Error Overflow Flag—This flag is set to 1 when at least one of the following events occurs: a) Memory errors are detected <i>and corrected</i> on CHI LRAM and interrupt flag LRCE_IF is already 1 b) Memory errors are detected <i>and corrected</i> on at least two banks of CHI LRAM 0 No such event 1 Corrected Error overflow detected on CHI LRAM Note: Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
DRNE_OF	DRAM Non-Corrected Error Overflow Flag—This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected <i>but not corrected</i> on PE DRAM and interrupt flag DRNE_IF is already 1 b) Memory errors are detected <i>but not corrected</i> on at least two banks of the PE DRAM 0 No such event 1 Non-Corrected Error overflow detected on PE DRAM
DRCE_OF	DRAM Corrected Error Overflow Flag—This flag is set to 1 when at least one of the following events appears: a) Memory errors are detected <i>and corrected</i> on PE DRAM and interrupt flag DRCE_IF is already 1 b) Memory errors are detected <i>and corrected</i> on at least two banks of PE DRAM 0 No such event 1 Corrected Error overflow detected on PE DRAM

Table 1049. FR_EEIFER field descriptions (continued)

Field	Description
Error Interrupt Flags	
LRNE_IF	LRAM Non-Corrected Error Interrupt Flag —This interrupt flag is set to 1 when a memory error is <i>detected but not corrected</i> on the CHI LRAM. 0 No such event 1 Non-Corrected Error detected on CHI LRAM
LRCE_IF	LRAM Corrected Error Interrupt Flag —This interrupt flag is set to 1 when a memory error is <i>detected and corrected</i> on the CHI LRAM. 0 No such event 1 Corrected Error detected on CHI LRAM Note: Error Correction is not implemented on CHI LRAM, so the flag will never be asserted.
DRNE_IF	DRAM Non-Corrected Error Interrupt Flag —This interrupt flag is set to 1 when a memory error is <i>detected but not corrected</i> on PE DRAM. 0 No such event 1 Non-Corrected Error detected on PE DRAM
DRCE_IF	DRAM Corrected Error Interrupt Flag —This interrupt flag is set to 1 when a memory error is <i>detected and corrected</i> on PE DRAM. 0 No such event 1 Corrected Error detected on PE DRAM
Error Interrupt Enables	
LRNE_IE	LRAM Non-Corrected Error Interrupt Enable —This flag controls if the LRAM Non-Corrected Error Interrupt line is asserted when the LRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
LRCE_IE	LRAM Corrected Error Interrupt Enable —This flag controls if the LRAM Corrected Error Interrupt line is asserted when the LRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
DRNE_IE	DRAM Non-Corrected Error Interrupt Enable —This flag controls if the DRAM Non-Corrected Error Interrupt line is asserted when the DRNE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line
DRCE_IE	DRAM Corrected Error Interrupt Enable —This flag controls if the DRAM Corrected Error Interrupt line is asserted when the DRCE_IF flag is set. 0 Disable interrupt line 1 Enable interrupt line

51.5.2.72 ECC Error Report and Injection Control Register (FR_EERICR)

Figure 1041. ECC Error Report and Injection Control Register (FR_EERICR)

Base + 0x00F2

Write: ERS: Anytime

ERM, EIM, EIE: IDL

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register configures the error injection and error reporting and provides the selector for the content of the report registers.

Table 1050. FR_EERICR Field Descriptions

Field	Description
BSY	Register Update Busy —This field indicates the current state of the ECC configuration update and controls the register write access condition IDL specified in “ Section 51.5.2.2, “Register write access.” 0 ECC configuration is idle 1 ECC configuration is running
ERS	Error Report Select —This field selects the content of the ECC Error reporting registers. 00 Show PE DRAM non-corrected error information 01 Show PE DRAM corrected error information 10 Show CHI LRAM non-corrected error information 11 Show CHI LRAM corrected error information
ERM	Error Report Mode —This bit configures the type of data written into the internal error report registers on the detection of a memory error. 0 Store data and code as delivered by ecc decoding logic 1 Store data and code as read from the memory
EIM	Error Injection Mode —This bit configures the ECC error injection mode. 0 Use FR_EEIDR[DATA] and FR_EEICR[CODE] as XOR distortion pattern for error injection 1 Use FR_EEIDR[DATA] and FR_EEICR[CODE] as write value for error injection
EIE	Error Injection Enable —This bit configures the ECC error injection on the memories. 0 Error injection disabled 1 Error injection enabled

51.5.2.73 ECC Error Report Address Register (FR_EERAR)

Figure 1042. ECC Error Report Address Register (FR_EERAR)

Base + 0x00F4

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MID	BANK			ADDR											
W																
Reset	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the memory identifier, bank, and address for which the memory error is reported.

Table 1051. FR_EERAR Field Descriptions

Field	Description
MID	Memory Identifier —This flag provides the memory instance for which the memory error is reported. 0 PE DRAM 1 CHI LRAM
BANK	Memory Bank —This field provides the BANK for which the memory error is reported. 111 reset value, indicates no error found after reset. For MID = 0: 000 PE DRAM [7:0] 001 PE DRAM [15:8] Others—not used For MID = 1: Refer to Table 1052 for the assignment of the LRAM banks.
ADDR	Memory Address —This field provides the address of the failing memory location.

Table 1052. LRAM bank value for MID = 1

BANK	Register		
000	FR_MBCCFR(2n)	FR_MBDOR(6n)	FR_LEETR0

111			

51.5.2.74 ECC Error Report Data Register (FR_EERDR)

Figure 1043. ECC Error Report Data Register (FR_EERDR)

Base + 0x00F6

This register provides the data related information of the reported memory read access. The assignment of the bits depends on the selected memory and memory bank as shown in [Table 1054](#).

Table 1053. FR_EERDR field descriptions

Field	Description
DATA	Data —The content of this field depends on the report mode selected by FR_EERICR[ERM]. ERM = 0: Ecc Data, shows data as generated by the ecc decoding logic ERM = 1: Memory Data, shows data as read from the memory

Table 1054. Valid bits in FR_EERDR[DATA] / FR_EEIDR[DATA] field

MEM	BANK	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PE DRAM	0									PE DRAM[7:0]

51.5.2.75 ECC Error Report Code Register (FR_EERCR)

Figure 1044. ECC Error Report Code Register (FR_EERCR)

Base + 0x00F8

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	CODE				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register provides the ECC-related information of the reported memory read access.

Table 1055. FR_EERSR field descriptions

Field	Description
CODE	Code —The content of this field depends on the report mode selected by FR_EERICR[ERM]. ERM = 0: Syndrome. Shows the ECC syndrome generated by the ECC decoding logic. The coding of the PE DRAM syndrome is shown in Section 51.6.24.2.2: PE DRAM syndrome . The coding of the CHI LRAM syndrome is shown in Section 51.6.24.2.4: CHI LRAM syndrome . ERM = 1: Checkbits. Shows the ecc checkbits read from the memory.

51.5.2.76 ECC Error Injection Address Register (FR_EEIAR)

Figure 1045. ECC Error Injection Address Register (FR_EEIAR)

Base + 0x00FA

Write: IDL

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W	MID	BANK			ADDR											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the memory module, bank, and address where the ECC error has to be injected.

Table 1056. FR_EEIAR field descriptions

Field	Description
MID	Memory Identifier —This flag defines the memory instance for ECC error injection. 0 PE DRAM 1 CHI LRAM
BANK	Memory Bank —This field defines the memory bank for ECC error injection. For MID = 0: 000 BANK0: PE DRAM [7:0] 001 BANK1: PE DRAM [15:8] Others reserved For MID = 1: Refer to Table 1052 for the assignment of the LRAM banks.
ADDR	Memory Address —This flag defines the memory address for ECC error injection.

51.5.2.77 ECC Error Injection Data Register (FR_EEIDR)

Figure 1046. ECC Error Injection Data Register (FR_EEIDR)

This register defines the data distortion pattern for the error injection write. The number of valid bits depends on the selected memory and memory bank as shown in [Table 1054](#).

Table 1057. FR_EEIDR field descriptions

Field	Description
DATA	Data —The content of this field depends on the error injection mode selected by FR_EEICR[EIM]. EIM = 0: This field defines the XOR distortion pattern for the data written into the memory. EIM = 1: This field defines the data to be written into the memory.

Note: The effect of the error injected depends from the LRAM content at the address accessed and from the module internal usage of the data. Refer to [Section 51.6.24.3, "Memory error response"](#) for details.

51.5.2.78 ECC Error Injection Code Register (FR_EEICR)

Figure 1047. ECC Error Injection Code Register (FR_EEICR)

Base + 0x00FE												Write: IDL				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	CODE				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register defines the ECC code distortion pattern for the error injection write.

Table 1058. FR_EEICR field descriptions

Field	Description
CODE	Code —The content of this field depends on the error injection mode selected by FR_EEICR[EIM]. EIM = 0: This field defines the XOR distortion pattern for the ECC checkbits written into the memory. EIM = 1: This field defines the ECC checkbits written into the memory.

51.5.2.79 Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)

Figure 1048. Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)

Base + 0x0800 (FR_MBCCSR0)	Write: MTD: <i>POC:cnfig</i> or MB_DIS CMT: MB_LCK or MB_DIS EDT, LCKT, MBIE, MBIF: Normal mode
Base + 0x0808 (FR_MBCCSR1)	
...	
Base + 0x0BF8 (FR_MBCCSR127)	

Additional Reset: CMT, DUP, DVAL, MBIF: Message Buffer Disable

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	MTD	CMT	0	0	MBIE	0	0	0	DUP	DVAL	EDS	LCKS	MBIF
W					rwm	EDT	LCKT									w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The content of these registers comprises message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in [Section 51.6.6, “Individual message buffer functional description”](#).

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Table 1059. FR_MBCCSRn field descriptions

Field	Description
Message Buffer Configuration	
MTD	Message Buffer Transfer Direction —This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
Message Buffer Control	
CMT	Commit for Transmission —This bit indicates if the transmit message buffer data are ready for transmission. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
EDT	Enable/Disable Trigger —If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
LCKT	Lock/Unlock Trigger —If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
MBIE	Message Buffer Interrupt Enable —This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set. 0 Interrupt request generation disabled 1 Interrupt request generation enabled
Message Buffer Status	
DUP	Data Updated —This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and message buffer data field not updated 1 Frame Header and message buffer data field updated
DVAL	Data Valid —For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers, the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 Receive message buffer contains no valid frame data / message is transmitted for the first time 1 Receive message buffer contains valid frame data / message will be transferred again
EDS	Enable/Disable Status —This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled 1 Message buffer is enabled
LCKS	Lock Status —This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application 1 Message buffer is locked by the application
MBIF	Message Buffer Interrupt Flag —This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled In Functional Test Mode writing a 1 toggles the interrupt flag.

51.5.2.80 Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)

Figure 1049. Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)

Base + 0x0802 (FR_MBCCFR0)

Base + 0x080A (FR_MBCCFR1)

16-bit write access required

Write: *POC:config* or MB_DIS

...

Base + 0x0BFA (FR_MBCCFR127)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MTM	CHA	CHB	CCF	CCFMSK					CCFVAL						
W				E												
Reset	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to [Section 51.6.7.1, “Message buffer cycle counter filtering”](#).

Table 1060. FR_MBCCFRn field descriptions

Field	Description
MTM	Message Buffer Transmission Mode —This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event Transmission mode 1 State Transmission mode
CHA CHB	Channel Assignment —These control bits define the channel assignment and control the receive and transmit behavior of the message buffer according to Table 1061 .
CCFE	Cycle Counter Filtering Enable —This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled
CCFMSK	Cycle Counter Filtering Mask —This field defines the filter mask for the cycle counter filtering.
CCFVAL	Cycle Counter Filtering Value —This field defines the filter value for the cycle counter filtering.

Table 1061. Channel assignment description

CHA	CHB	Transmit message buffer		Receive message buffer	
		Static segment	Dynamic segment	Static segment	Dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Note: *If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the message buffer configuration is illegal and the result of the message buffer search is not defined.*

51.5.2.81 Message Buffer Frame ID Registers (FR_MBFIDRn)

Figure 1050. Message Buffer Frame ID Registers (FR_MBFIDRn)

W																
Reset	0	0	0	0	0	0	0	0	-	-	-	-	-	-	-	-

Table 1063. FR_MBIDXn field descriptions

Field	Description
MBIDX	Message Buffer Index —This field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer. The application writes the index of the initially associated message buffer header field into this register. The CC updates this register after frame reception or transmission. Legal Values are $0 \leq i \leq 131$. Illegal values will be detected during the message buffer search.

51.5.2.83 Message Buffer Data Field Offset Registers (FR_MBDORn)

Figure 1052. Message Buffer Data Field Offset Registers (FR_MBDORn)

Base + 0x1000 (FR_MBDOR0)

Base + 0x1002 (FR_MBDOR1)

16-bit write access required

Write: *POC:config*

...

Base + 0x1106 (FR_MBDOR131)

Table 1064. FR_MBDORn field descriptions

Field	Description
MBDO	Message Buffer Data Field Offset —This field provides the data field offset belonging to a particular Message Buffer Index. For configuration constraints see Section 51.7.1.2, "Configure data field offsets" .

51.5.2.84 LRAM ECC Error Test Registers (FR_LEETRn)

Figure 1053. LRAM ECC Error Test Registers (FR_LEETRn)

Base + 0x1108 (FR_LEETR0)

...

16-bit write access required

Write: *Anytime*

Base + 0x1112 (FR_LEETR5)

Table 1065. FR_LEETRn field descriptions

Field	Description
LEETD	LRAM ECC Error Test Data —This field contains the LRAM data belonging to the test register located in LRAM Bank n.

51.5.2.85 Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)

Figure 1054. Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)

Base + 0x00E2

Write: Anytime

Figure 1056. Stop Watch Count Low Register (FR_STPWLR)

Table 1067. FR_STPWR field descriptions

Field	Description
STPW	Stop Watch Count Register —This is the value of the stop watch counter running on system clock. This starts on cycle start even and stops on an external event “OS_tick”. For details see Section 51.6.26, “StopWatch function . This is a read reset type register, which means that when all the 32 bits are read, it automatically clears.

51.6 Functional description

This section provides a detailed description of the functionality implemented in the CC.

51.6.1 Message buffer concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts: the *message buffer control data* and the *physical message buffer*. The message buffer control data is located in dedicated registers. The structure of the message buffer control data depends on the message buffer type, described in [Section 51.6.3, "Message Buffer Types"](#). The physical message buffer is located in the FlexRay memory area and is described in [Section 51.6.2, "Physical message buffer"](#).

51.6.2 Physical message buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area. The structure of a physical message buffer is depicted in [Figure 1053](#).

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

Figure 1057. Physical message buffer structure

51.6.2.1 Message buffer header field

The message buffer header field is a contiguous region in the FlexRay memory area that occupies eight bytes. It contains the frame header and the slot status. Its structure is shown in [Figure 1057](#). The physical start address SADR_MBHF of the message buffer header field must be 16-bit aligned.

51.6.2.1.1 Frame header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the usage and the content of the frame header is provided in [Section 51.6.5.2.1, "Frame header description"](#).

51.6.2.1.2 Slot status

The slot status occupies the last 2 bytes of the message buffer header field. It provides the slot and frame status-related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in [Section 51.6.5.2.2, “Slot status description](#).

51.6.2.2 Message buffer data field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in [Section 51.6.3, “Message Buffer Types](#).

51.6.3 Message Buffer Types

The CC provides three different types of message buffers.

- Individual Message Buffers
- Receive Shadow Buffers
- Receive FIFO Buffers

For each message buffer type, the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

51.6.3.1 Individual Message Buffers

The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in [Section 51.6.6, “Individual message buffer functional description](#).

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in [Figure 1058](#).

Each individual message buffer has a message buffer number n assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number n is controlled by the registers FR_MBCCSR n , FR_MBCCFR n , FR_MBFIDR n , and FR_MBIDXR n .

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field, MBIDX, in the [Message Buffer Index Registers \(FR_MBIDXR \$n\$ \)](#). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to [Equation 39](#).

$$\text{Equation 39} \quad \text{SADR_MBHF} = (\text{FR_MBIDXR}[\text{MBIDX}] \times 8) + \text{SMBA}$$

The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i , the FR_MBDOR i contains the offset of the corresponding message buffer data field with respect to the CC FlexRay

memory area base address as provided by SMBA field in the [System Memory Base Address Register \(FR_SYMBADR\)](#).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to [Equation 40](#).

$$\text{Equation 40} \quad \text{SADR_MBDF} = [\text{Data Field Offset}] + \text{SMBA}$$

The FR_MBDORn are stored in the module internal memory LRAM. Refer to [Section 51.7.2.3, "CHI LRAM initialization"](#) for the setup of the data field offset values.

Figure 1058. Individual message buffer structure

51.6.3.1.1 Individual message buffer segments

The set of the individual message buffers can be split up into two message buffer segments using the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#). All individual message buffers with a message buffer number $n \leq \text{FR_MBSSUTR}[\text{LAST_MB_SEG1}]$ belong to the first message buffer segment. All individual message buffers with a message buffer number $n > \text{FR_MBSSUTR}[\text{LAST_MB_SEG1}]$ belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- All physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length.
- The minimum length of the message buffer data field for individual message buffers in the first message buffer segment is $2 \times \text{FR_MBDSR}[\text{MBSEG1DS}]$ bytes.
- The minimum length of the message buffer data field for individual message buffers assigned to the second segment is $2 \times \text{FR_MBDSR}[\text{MBSEG2DS}]$ bytes..

51.6.3.2 Receive shadow buffers

The receive shadow buffers are required for the individual message buffers' frame reception process. The CC provides four receive shadow buffers: one receive shadow buffer per channel and per message buffer segment.

Each receive shadow buffer consists of two parts: the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in [Figure 1059](#). The four internal shadow buffer control registers can be accessed by the [Receive Shadow Buffer Index Register \(FR_RSBIR\)](#).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the [Receive Shadow Buffer Index Register \(FR_RSBIR\)](#). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to [Equation 41](#).

Equation 41 $SADR_MBHF = (FR_RSBIR[RSBIDX] \times 8) + SMBA$

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in [Receive Shadow Buffer Index Register \(FR_RSBIR\)](#).

Figure 1059. Receive shadow buffer structure

51.6.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in [Figure 1060](#).

The connection between the receive FIFO control registers and the set of physical message buffers is established by the [Receive FIFO Start Index Register \(FR_RFSIR\)](#), the [Receive FIFO Depth and Size Register \(FR_RFDSR\)](#), and the [Receive FIFO A Read Index Register \(FR_RFARIR\)/Receive FIFO B Read Index Register \(FR_RFBRIR\)](#).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM], refer to [Section 51.5.2.4, "Module Configuration Register \(FR_MCR\)"](#).

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to [Equation 42](#).

$$\text{Equation 42} \quad \text{SADR_MBHF}[1] = (8 \times \text{FR_RFSIR}[\text{SIDX}]) + \text{SMBA}$$

The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according to [Equation 43](#).

$$\text{Equation 43} \quad \text{SADR_MBHF}[n] = (8 \times (\text{FR_RFSIR}[\text{SIDX}] + \text{FR_RFDSR}[\text{FIFO_DEPTH}])) + \text{SMBA}$$

The required information to access the current entry of the FIFO is given in the following registers:

- The registers [Receive FIFO A Read Index Register \(FR_RFARIR\)](#) and [Receive FIFO B Read Index Register \(FR_RFBRIR\)](#) provide the index of the physical message buffer belonging to the current entry.

The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

$$\text{Equation 44} \quad \text{RF_DFO}[X] = \text{FR_RFSDOR}[X] + (\text{FR_RFDSR}[X][\text{ENTRY_SIZE}] \times 2) \times i - \text{FR_RFSIDX}[X]$$

Note: The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to [Section 51.6.9.8, "FIFO update"](#) for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

Figure 1060. Receive FIFO structure

Note: The actual values of the data field offsets $RF_DFO[A/B]$ need to be calculated according to Equation 44. They are not stored in a register.

51.6.3.4 Message buffer configuration and control data

This section describes the configuration and control data for each message buffer type.

51.6.3.4.1 Individual message buffer configuration data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

51.6.3.4.1.1 Common configuration data

The set of common configuration data for individual message buffers is located in the following registers.

- **Message Buffer Data Size Register (FR_MBDSR)**
The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.
- **Message Buffer Segment Size and Utilization Register ($FR_MBSSUTR$)**
The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are

used. For more details, see [Section 51.6.3.1.1, “Individual message buffer segments](#).

51.6.3.4.1.2 Specific configuration data

The set of message buffer specific configuration data for individual message buffers is located in the following registers.

- [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#)
The MTD bit configures the message buffer type.
- [Message Buffer Cycle Counter Filter Registers \(FR_MBCCFRn\)](#)
The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.
- [Message Buffer Frame ID Registers \(FR_MBFIDRn\)](#)
For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.
- [Message Buffer Index Registers \(FR_MBIDXRn\)](#)
This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.

51.6.3.5 Individual message buffer control data

During normal operation, each individual message buffer can be controlled by the CMT, LCKT, EDT, and MBIE control and trigger bits in the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#).

51.6.3.6 Receive shadow buffer configuration data

Before the individual message buffers can receive frames, the receive shadow buffers must be configured. The configuration data are provided by the [Receive Shadow Buffer Index Register \(FR_RSBIR\)](#). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

51.6.3.7 Receive FIFO control and configuration data

This section describes the configuration and control data for the two receive FIFOs.

51.6.3.7.1 Receive FIFO configuration data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- [Receive FIFO Periodic Timer Register \(FR_RFPTR\)](#)

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- Receive FIFO Watermark and Selection Register (FR_RFWMSR)
- Receive FIFO Start Index Register (FR_RFSIR)
- Receive FIFO Start Data Offset Register (FR_RFSDOR)
- Receive FIFO Depth and Size Register (FR_RFDSR)
- Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
- Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
- Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
- Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
- Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

51.6.3.7.2 Receive FIFO control data

The application can access the FIFOs at any time using the control bits in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

51.6.3.7.3 Receive FIFO status data

The current status of the receive FIFO is provided in the following registers:

- Global Interrupt Flag and Enable Register (FR_GIFER)
- Receive FIFO A Read Index Register (FR_RFARIR)
- Receive FIFO B Read Index Register (FR_RFBRIR)
- Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

51.6.4 FlexRay memory area layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].

51.6.4.1 FlexRay memory area layout (FR_MCR[FAM] = 0)

[Figure 1061](#) shows an example layout for the FIFO address mode FR_MCR[FAM] = 0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is a maximum of 64 KB.
- The FlexRay memory area starts at a 16 byte boundary.

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

Figure 1061. Example of FlexRay memory area layout (FR_MCR[FAM] = 0)

51.6.4.2 FlexRay memory area layout (FR_MCR[FAM] = 1)

Figure 1062 shows an example layout for the FIFO address mode FR_MCR[FAM] = 1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

$$\text{Equation 47} \quad \text{SADR_MBHF} = (i \times 8) + \text{FR_SYMBADR}[SMBA]; (0 \leq i \leq 1023)$$

3. The message buffer header fields for each FIFO must be a contiguous area.

51.6.4.4 Message buffer header area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill [Equation 48](#).

$$\text{Equation 48} \quad \text{SADR_MBHF} = (i \times 8) + \text{FR_SYMBADR}[SMBA]; (0 \leq i \leq 131)$$

51.6.4.5 FIFO message buffer header area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill [Equation 49](#).

$$\text{Equation 49} \quad \text{SADR_MBHF} = (i \times 8) + \text{FR_RFSYMBADR}[SMBA]; (0 \leq i \leq 1023)$$

2. The message buffer header fields for each FIFO have to be a contiguous area.

51.6.4.6 Message buffer data area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

51.6.4.7 Sync frame table area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to [Section 51.6.12, "Sync frame ID and sync frame deviation tables"](#) for the description of the sync frame table area.

51.6.5 Physical message buffer description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer: the message buffer header field and the message buffer data field.

51.6.5.1 Message buffer protection and data consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

51.6.5.2 Message buffer header field description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in [Section 51.6.2.1, "Message buffer header field"](#). Each message buffer header field consists of two sections: the frame header section and the slot status section.

51.6.5.2.1 Frame header description

51.6.5.2.1.1 Frame header content

The semantic and content of the frame header section depends on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in [Figure 1063](#). A detailed description is given in [Table 1069](#).

Figure 1063. Frame header structure (receive message buffer and receive FIFO)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID										
0x2	0	0	CYCCNT						0	PLDLEN						
0x4	0	0	0	0	0	HDCRC										

The structure of the frame header in the message buffer header field for transmit message buffers is given in [Figure 1064](#). A detailed description is given in [Table 1070](#). The checks that will be performed are described in [Frame Header Checks](#).

Figure 1064. Frame header structure (transmit message buffer)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	
0x0	R	PPI	NUF	SYF	SUF	FID											
0x2			CYCCNT								PLDLEN						
0x4						HDCRC											

 = not used

 = checked

 = checked if static slot

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in [Figure 1065](#).

Figure 1065. Frame header structure (transmit message buffer for key slot)

51.6.5.2.1.2 Frame Header Access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in [Table 1068](#). This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 1068. Frame header write access constraints (transmit message buffer)

Field	Static segment	Dynamic segment
FID	<i>POC:config</i> or MB_DIS	
PPI, PLDLEN, HDCRC	<i>POC:config</i> or MB_DIS or	MB_LCK

51.6.5.2.1.3 Frame Header Checks

As shown in [Figure 1064](#) and [Figure 1065](#), not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding [Message Buffer Frame ID Registers \(FR_MBFIDRn\)](#). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag, FID_EF, in the [CHI Error Flag Register \(FR_CHIERFR\)](#). The value of the FID field will be ignored and replaced by the value provided in the [Message Buffer Frame ID Registers \(FR_MBFIDRn\)](#).

For transmit message buffers assigned to the *static* segment, the PLDLEN value must be equal to the value of the payload_length_static field in the [Protocol Configuration Register 19 \(FR_PCR19\)](#). If this is not fulfilled, the static payload length error flag SPL_EF in the [CHI Error Flag Register \(FR_CHIERFR\)](#) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the `max_payload_length_dynamic` field in the [Protocol Configuration Register 24 \(FR_PCR24\)](#). If this is not fulfilled, the dynamic payload length error flag `DPL_EF` in the [CHI Error Flag Register \(FR_CHIERFR\)](#) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 1069. Frame header field descriptions (receive message buffer and receive FFO)

Field	Description
R	Reserved Bit —This is the value of the Reserved bit of the received frame stored in the message buffer.
PPI	Payload Preamble Indicator —This is the value of the Payload Preamble Indicator of the received frame stored in the message buffer.
NUF	Null Frame Indicator —This is the value of the Null Frame Indicator of the received frame stored in the message buffer.
SYF	Sync Frame Indicator —This is the value of the Sync Frame Indicator of the received frame stored in the message buffer.
SUF	Startup Frame Indicator —This is the value of the Startup Frame Indicator of the received frame stored in the message buffer.
FID	Frame ID —This is the value of the Frame ID field of the received frame stored in the message buffer.
CYCCNT	Cycle Count —This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	Payload Length —This is the value of the Payload Length field of the received frame stored in the message buffer.
HDCRC	Header CRC —This is the value of the Header CRC field of the received frame stored in the message buffer.

Table 1070. Frame header field descriptions (transmit message buffer)

Field	Description
R	Reserved Bit —This bit is not used. The value of the Reserved bit is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .
PPI	Payload Preamble Indicator —This bit provides the value of the Payload Preamble Indicator for the frame transmitted from the message buffer.
NUF	Null Frame Indicator —This bit is not used, the value of the Null Frame Indicator is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .
SYF	Sync Frame Indicator —This bit is not used. The value of the Sync Frame Indicator is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .
SUF	Startup Frame Indicator —This bit is not used. The value of the Startup Frame Indicator is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .
FID	Frame ID —This field is checked as described in Frame Header Checks .
CYCCNT	Cycle Count —This field is not used, the value of the transmitted Cycle Count field is taken from the internal communication cycle counter.

Table 1070. Frame header field descriptions (transmit message buffer)

Field	Description
PLDLEN	Payload Length —This field is checked and used as described in Frame Header Checks .
HDCRC	Header CRC —This field provides the value of the Header CRC field for the frame transmitted from the message buffer.

51.6.5.2.2 Slot status description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depends on the message buffer type.

51.6.5.2.2.1 Receive message buffer and receive FIFO slot status description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given by [Table 1071](#).

Table 1071. Receive message buffer slot status content

Receive message buffer type	Slot status content
Individual Receive Message Buffer assigned to both channels FR_MBCCFRn[CHA] = 1 and FR_MBCCFRn[CHB] = 1	see Figure 1066
Individual Receive Message Buffer assigned to channel A FR_MBCCFRn[CHA] = 1 and FR_MBCCFRn[CHB] = 0	see Figure 1067
Individual Receive Message Buffer assigned to channel B FR_MBCCFRn[CHA] = 0 and FR_MBCCFRn[CHB] = 1	see Figure 1068
Receive FIFO Channel A Message Buffer	see Figure 1067
Receive FIFO Channel B Message Buffer	see Figure 1068

The meaning of the bits in the slot status structure is explained in [Table 1072](#).

**Figure 1066. Receive message buffer slot status structure (ChAB)****Figure 1067. Receive message buffer slot status structure (ChA)**

Figure 1068. Receive message buffer slot status structure (ChB)

Table 1072. Receive message buffer slot status field description

Field	Description
Common Message Buffer Status Bits	
VFB	Valid Frame on Channel B —Protocol-related variable: <i>vSS!ValidFrame</i> channel B 0 <i>vSS!ValidFrame</i> = 0 1 <i>vSS!ValidFrame</i> = 1
SYB	Sync Frame Indicator Channel B —Protocol-related variable: <i>vRF!Header!SyFIndicator</i> channel B 0 <i>vRF!Header!SyFIndicator</i> = 0 1 <i>vRF!Header!SyFIndicator</i> = 1
NFB	Null Frame Indicator Channel B —Protocol-related variable: <i>vRF!Header!NFIndicator</i> channel B 0 <i>vRF!Header!NFIndicator</i> = 0 1 <i>vRF!Header!NFIndicator</i> = 1
SUB	Startup Frame Indicator Channel B —Protocol-related variable: <i>vRF!Header!SuFIndicator</i> channel B 0 <i>vRF!Header!SuFIndicator</i> = 0 1 <i>vRF!Header!SuFIndicator</i> = 1
SEB	Syntax Error on Channel B —Protocol-related variable: <i>vSS!SyntaxError</i> channel B 0 <i>vSS!SyntaxError</i> = 0 1 <i>vSS!SyntaxError</i> = 1
CEB	Content Error on Channel B —Protocol related variable: <i>vSS!ContentError</i> channel B 0 <i>vSS!ContentError</i> = 0 1 <i>vSS!ContentError</i> = 1
BVB	Boundary Violation on Channel B —Protocol-related variable: <i>vSS!BViolation</i> channel B 0 <i>vSS!BViolation</i> = 0 1 <i>vSS!BViolation</i> = 1
CH	Channel first valid received —This status bit applies only to receive message buffers assigned to the static segment and to both channels. It indicates the channel that has received the <i>first valid</i> frame in the slot. This flag is set to 0 if no valid frame was received at all in the subscribed slot. 0 First valid frame received on channel A, or no valid frame received at all 1 First valid frame received on channel B
VFA	Valid Frame on Channel A —Protocol-related variable: <i>vSS!ValidFrame</i> channel A 0 <i>vSS!ValidFrame</i> = 0 1 <i>vSS!ValidFrame</i> = 1

51.6.5.2.2.2 Transmit Message Buffer Slot Status Description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given by [Table 1073](#).

Table 1073. Transmit message buffer slot status content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Figure 1069
Individual Transmit Message Buffer assigned to channel A FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0	see Figure 1070
Individual Transmit Message Buffer assigned to channel B FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1	see Figure 1071

The meaning of the bits in the slot status structure is described in [Table 1074](#).

51.6.5.3 Message buffer data field description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in [Table 1075](#). The structure of the message buffer data field is given in [Figure 1072](#).

Table 1075. Message buffer data field minimum length

Physical message buffer assigned to	Minimum length defined by
Individual message buffer in segment 1	FR_MBDSR[MBSEG1DS]
Receive shadow buffer in segment 1	FR_MBDSR[MBSEG1DS]
Individual message buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive shadow buffer in segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note: The CC will not access any locations outside the message buffer data field boundaries given by [Table 1075](#).

Figure 1072. Message buffer data field structure

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	DATA0 / MID0 / NMV0								DATA1 / MID1 / NMV1							
0x2	DATA2 / NMV2								DATA3 / NMV3							
...	...								...							
0xN-2	DATA N-2								DATA N-1							

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

51.6.5.3.1 Message buffer data field read access

For transmit message buffers, the CC will not modify the content of the message buffer data field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the [Message Buffer Index Registers \(FR_MBIDXn\)](#). While the message buffer is locked, the CC will not update the message buffer data field.

For receive FIFOs, the application can read the message buffer indicated by the [Receive FIFO A Read Index Register \(FR_RFARIR\)](#) or the [Receive FIFO B Read Index Register \(FR_RFBIR\)](#) when the related fill levels in the [Receive FIFO Fill Level and POP Count Register \(FR_RFFLPCR\)](#) indicate an non-empty FIFO.

51.6.5.3.2 Message buffer data field write access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in [Table 1076](#).

Table 1076. Frame data write access constraints

Field	CC/MB State
DATA, MID, NMV	<i>POC:config</i> or MB_DIS or MB_LCK

Table 1077. Frame data field descriptions

Field	Description
DATA 0, DATA 1, ... DATA N–1	Message Data —Provides the message data received or to be transmitted. For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	Message Identifier —If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.
NMV 0, NMV 1, ... NMV 11	Network Management Vector —If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. <i>Note: The MID and NMV bytes replace the corresponding DATA bytes.</i>

51.6.6 Individual message buffer functional description

The CC provides the following basic types of individual message buffers:

- Transmit message buffers
- Receive message buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in [Section 51.6.3.4.1, "Individual message buffer configuration data"](#).

51.6.6.1 Individual message buffer configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

51.6.6.1.1 Common configuration data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. This data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the [Message Buffer Data Size Register \(FR_MBDSSR\)](#).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the [Receive Shadow Buffer Index Register \(FR_RSBR\)](#).

51.6.6.1.2 Specific configuration data

The second part of the message buffer configuration data is specific for each message buffer.

This data can be changed only when either

- The protocol is in the *POC:config* state, or
- The message buffer is disabled (that is, FR_MBCCSRn[EDS] = 0)

The individual message buffer type is defined by the MTD and MBT bits in the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#) as given in [Table 1078](#).

Table 1078. Individual message buffer types

FR_MBCCSRn		Individual message buffer description
MTD	MBT	
0	0	Receive message buffer
0	1	Reserved
1	0	Transmit message buffer
1	1	Reserved

The message-buffer-specific configuration data includes the following:

1. MTD bits in the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#)
2. All fields in the [Message Buffer Cycle Counter Filter Registers \(FR_MBCCFRn\)](#)
3. All fields in the [Message Buffer Frame ID Registers \(FR_MBFIDRn\)](#)
4. All fields in the [Message Buffer Index Registers \(FR_MBIDXRn\)](#)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions. See [Section 51.6.6.2, “Transmit message buffers”](#) and [Section 51.6.6.3, “Receive message buffers”](#) for further information.

51.6.6.2 Transmit message buffers

The section provides a detailed description of the functionality of single-buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number *n* is configured to be a transmit message buffer by the following settings:

- FR_MBCCSRn[MBT] = 0 (single buffered message buffer)
- FR_MBCCSRn[MTD] = 1 (transmit message buffer)

51.6.6.2.1 Access regions

For certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in [Figure 1073](#). A description of the regions is given in [Table 1080](#). If a region is active as indicated in [Table 1081](#), the access scheme given for that region applies to the message buffer.

Figure 1073. Transmit message buffer access regions

Table 1079. Transmit message buffer access regions description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration
MSG	Read/write	—	Message data and slot status access
NF	—	Read-only	Message header access for null frame transmission
TX	—	Read/write	Message transmission and slot status update
CM	—	Read-only	Message buffer validation
SR	—	Read-only	Message buffer search

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT], and the interrupt enable bit FR_MBCCSRn[MBIE], are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in [Figure 1074](#). A description of the states is given in [Table 1080](#), which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

51.6.6.2.2 Message buffer states

This section describes the transmit message buffer states and provides a state diagram.

```

State	FR_MBCCSRn		Access region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	CM, SR	Idle —Message Buffer is idle. Included in message buffer search
HDis	0	0	CFG	—	Disabled —Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked —Message Buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	SR	Locked—Application access to data, control, and status. Included in message buffer search.
CCSa	1	0	—	—	Slot Assigned—Message buffer assigned to next static slot. Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	—	Locked and Slot Assigned—Application access to data, control, and status.Message buffer assigned to next static slot.
CCNf	1	0	—	NF	Null Frame Transmission—Header is used for null frame transmission.
HLckCCNf	1	1	MSG	NF	Locked and Null Frame Transmission—Application access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	—	CM	Message Available—Message buffer is assigned to next slot and cycle counter filter matches.

Table 1080. Transmit message buffer state description (continued)

State	FR_MBCCSRn		Access region		Description
	EDS	LCKS	Appl.	Module	
HLckCCMa	1	1	MSG	—	Locked and Message Available—Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	—	TX	Message Transmission—Message buffer data transmit. Payload data from buffer transmitted.
CCSu	1	0	—	TX	Status Update—Message buffer status update. Update of status flags, the slot status field, and the header index.

51.6.6.2.3 Message buffer transitions

51.6.6.2.3.1 Application transitions

The application transitions can be triggered by the application using the commands described in [Table 1081](#). The application issues the commands by writing to the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

Message Buffer Enable and Disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

Message Buffer Lock and Unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the [CHI Error Flag Register \(FR_CHIERFR\)](#) is set.

Table 1081. Transmit message buffer application transitions

Transition	Command	Condition	Description
HE	FR_MBCCSRn[EDT] := 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.

Table 1081. Transmit message buffer application transitions (continued)

Transition	Command	Condition	Description
HL	FR_MBCCSRn[LCKT] = 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

51.6.6.2.3.2 Module transitions

The module transitions that can be triggered by the CC are described in [Table 1082](#). Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 1082. Transmit message buffer module transitions

Transition	Condition	Description
SA	Slot match and static slot	Slot Assigned—Message buffer is assigned to next static slot.
MA	Slot match and CycleCounter match	Message Available—Message buffer is assigned to next slot and cycle counter filter matches.
TX	Slot start and FR_MBCCSRn[CMT] = 1	Transmission Slot Start—Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	Status updated	Status Updated—Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	Static slot start	Static Slot Start—Start of static slot.
DSS	Dynamic slot start or symbol window start or NIT start	Dynamic Slot or Segment Start—Start of dynamic slot or symbol window or NIT.
SSS	Slot start or symbol window start or NIT start	Slot or Segment Start—Start of static slot or dynamic slot or symbol window or NIT.

51.6.6.2.3.3 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of [Table 1083](#), the module transitions have a higher priority than the application transitions. For all states except the CCMA state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and, subsequently, the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions are given in the second part of [Table 1083](#).

Table 1083. Transmit message buffer transition priorities

State	Priorities	Description
module vs. application		
Idle, HLck	SA > HD	Slot Assigned > Message Buffer Disable
	MA > HD	Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
Module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS	Transmission Slot Start > Static Slot Start
	TX > DSS	Transmission Slot Start > Dynamic Slot Start

51.6.6.2.4 Transmit message setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit, CMT, in the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#). The physical access to the message buffer data field is described in [Section 51.6.3.1, "Individual Message Buffers"](#).

As indicated by [Table 1074](#), the application will write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the following states: HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in [Table 1074](#). The state change is indicated through the FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters the HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa state, the FR_MBCCSRn[DVAL] flag is negated.

51.6.6.2.5 Message transmission

As a result of the message buffer search described in [Section 51.6.7, "Individual message buffer search"](#), the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. The message buffer is in the message available state CCMa
2. The message data is still valid (that is, FR_MBCCSRn[CMT] = 1)

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in [Figure 1075](#). In this example, the message buffer with message buffer number *n* is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid (that is, FR_MBCCSRn[CMT] = 1).

Figure 1075. Message transmission timing

Figure 1076. Message transmission from HLck state with unlock

The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items

1. The message buffer segment that the message buffer is assigned to, as defined by the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#).
2. The message buffer data field size, as defined by the related field of the [Message Buffer Data Size Register \(FR_MBDSDR\)](#)
3. The value of the PLDLEN field in the message buffer header field, as described in [Section 51.6.5.2.1, "Frame header description"](#)

If a message buffer is assigned to message buffer segment 1, and $PLDLEN > MBSEG1DS$, then $2 \times MBSEG1DS$ bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If $PLDLEN \leq MBSEG1DS$, the CC reads and transfers $2 \times PLDLEN$ bytes. The same holds for segment 2 and $MBSEG2DS$.

51.6.6.2.6 Null frame transmission

A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the $FR_MBFIDRn[FID]$ set to S and $FR_MBCCFRn[CHA]$ set to 1. A null frame is transmitted in the static slot s on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with $FR_MBFIDRn[FID] = S$ and $FR_MBCCFRn[CHA] = 1$ are either not committed (that is, $FR_MBCCSRn[CMT] = 0$), or are locked by the application (that is, $FR_MBCCSRn[LCKS] = 1$), or the cycle counter filter is enabled and does not match.

Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in [Section 51.6.7, "Individual message buffer search"](#), the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in [Figure 1077](#).

Figure 1077. Null frame transmission from Idle state

A message buffer timing and state change diagram for null frame transmission from HLck state is given in [Figure 1078](#).

Figure 1078. Null frame transmission from HLck state

If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in [Figure 1079](#).

Figure 1079. Null frame transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in [Figure 1080](#).

Figure 1080. Null frame transmission from Idle state with locking

51.6.6.2.7 Message buffer status update

After the end of each slot, the PE generates the slot status vector. Depending on the status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

51.6.6.2.7.1 Message buffer status update after complete message transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer was sent to the FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSRn[MBIF] to indicate the successful message transmission.

Depending on the Transmission Mode flag FR_MBCCFRn[MTM], the CC changes the commit flag FR_MBCCSRn[CMT] and the valid flag FR_MBCCSRn[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in *Event Transmission mode*. In this case, each committed message is transmitted only once. The commit flag FR_MBCCSRn[CMT] is cleared with the SU transition. If the FR_MBCCFRn[MTM] flag is asserted, the message buffer is in the *State Transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSRn[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSRn[DVAL] to indicate that the message will be transmitted again.

51.6.6.2.7.2 Message buffer status update after incomplete message transmission

The term *incomplete message transmission* refers to the fact that not all payload data that should be transmitted was sent to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than [pLatestTx](#).
2. The transmission slot did not exist in the dynamic segment at all.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those error occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the [Protocol Interrupt Flag Register 1 \(FR_PIFR1\)](#).

In either of these two cases, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

51.6.6.2.7.3 Message buffer status update after null frame transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

51.6.6.3 Receive message buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used, the related receive shadow buffer must be configured as described in [Section 51.6.3.2, "Receive shadow buffers"](#).

A receive message buffer is used to receive a message from the FlexRay bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application:

- Message data received
- Information about the reception process
- Status information about the slot in which the message was received

A individual message buffer with message buffer number n is configured as a receive message buffer by the following configuration settings:

- $FR_MBCCSRn[MTD] = 0$ (receive message buffer)

Both the application and the CC have access to certain message buffers. To ensure data consistency, a message buffer locking scheme controls the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in [Figure 1081](#). A description of the regions is given in [Table 1084](#). If an region is active as indicated in [Table 1085](#), the access scheme given for that region applies to the message buffer.

Figure 1081. Receive message buffer access regions

Table 1084. Receive message buffer access region description

Region	Access from		Region used for
	Application	Module	
CFG	Read/write	—	Message buffer configuration, message data, and status access
MSG	Read/write	—	Message data, header, and status access
RX	—	Write-only	Message reception and status update
SR	—	Read-only	Message buffer search data

The trigger bits $FR_MBCCSRn[EDT]$ and $FR_MBCCSRn[LCKT]$ and the interrupt enable bit $FR_MBCCSRn[MBIE]$ are not under access control and can be accessed from the application at any time. The status bits $FR_MBCCSRn[EDS]$ and $FR_MBCCSRn[LCKS]$ are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in [Figure 1082](#). A description of the message buffer states is given in [Table 1080](#), which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

Figure 1082. Receive message buffer states

Table 1085. Receive message buffer states and access

State	FR_MBCCSRn		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	—	SR	Idle —Message buffer is idle. Included in message buffer search.
HDis	0	0	CFG	—	Disabled —Message buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	—	Disabled and Locked —Message buffer under configuration. Excluded from message buffer search.
HLck	1	1	MSG	—	Locked —Application access to data, control, and status. Included in message buffer search.
CCBs	1	0	—	—	Buffer Subscribed —Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	—	Locked and Buffer Subscribed —Application access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	—	—	Message Receive —Message data received into related shadow buffer.

Table 1085. Receive message buffer states and access (continued)

State	FR_MBCCSRn		Access from		Description
	EDS	LCKS	Appl.	Module	
HLckCCR _x	1	1	MSG	—	Locked and Message Receive—Application access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	—	RX	Status Update —Message buffer status update. Update of status flags, the slot status field, and the header index.

51.6.6.3.1 Message buffer transitions

51.6.6.3.1.1 Application transitions

The application transitions that can be triggered by the application using the commands are described in [Table 1081](#). The application issues the commands by writing to the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

51.6.6.3.1.2 Message buffer enable and disable

The enable and disable commands are issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in the CCBs, HLckCCBs, or CCR_x state, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

51.6.6.3.1.3 Message buffer lock and unlock

The lock and unlock commands are issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL while the message buffer is in the CCR_x state, the lock transition has no effect (command is ignored) and the message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the [CHI Error Flag Register \(FR_CHIERFR\)](#) is set.

Table 1086. Receive message buffer application transitions

Transition	Host command	Condition	Description
HE	FR_MBCCSRn[EDT] := 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable
HL	FR_MBCCSRn[LCKT] := 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock

51.6.6.3.1.4 Module Transitions

The module transitions that can be triggered by the CC are described in [Table 1087](#). Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 1087. Receive message buffer module transitions

Transition	Condition	Description
BS	Slot match and cyclecounter match	Buffer Subscribed—The message buffer filter matches next slot and cycle.
SLS	Slot start	Slot Start—Start of either Static Slot or Dynamic Slot.
SNS	Symbol window start or NIT start	Symbol Window or NIT Start—Start of either Symbol Window or NIT.
SSS	Slot start, symbol window start, or NIT start	Slot or Segment Start—Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	Status updated	Status Updated—Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

51.6.6.3.1.5 Transition priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in [Table 1088](#), the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the CCBs buffer subscribed state and the module triggers the SLS slot start transition at the same time that the application locks the message buffer through the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state, HLckCCRx.

Table 1088. Receive message buffer transition priorities

State	Priorities	Description
Module vs. Application		
Idle	BS > HD	Buffer subscribed > Message buffer disable
HLck	BS > HD	Buffer subscribed > Message buffer disable
CCRx	SSS > HL	Slot or segment start > Message buffer lock

51.6.6.3.2 Message reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffer is assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot, the module triggers the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data is written into the shadow buffers. For details on receive shadow buffers, see [Section 51.6.6.3.5, "Receive shadow buffer concept"](#). The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

51.6.6.3.3 Message buffer update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer is in the locked state HLckCCRx, no update will be performed. The received data is lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the [CHI Error Flag Register \(FR_CHIERFR\)](#).

If a message buffer was in the CCRx state, it is now in the CCSu state. After the evaluation of the slot status provided by the PE, the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to, as described in [Table 1091](#).

Table 1089. Receive message buffer update

vSS!ValidFrame	vRF!Header!NFIndicator	Update description
1	1	Valid non-null frame received. – Message Buffer Data field updated. – Frame Header field updated. – Slot Status field updated. – DUP = 1 – DVAL = 1 – MBIF = 1
1	0	Valid null frame received. – Message Buffer Data field <i>not</i> updated. – Frame Header field <i>not</i> updated. – Slot Status field updated. – DUP = 0 – DVAL <i>not</i> changed – MBIF = 1

Table 1089. Receive message buffer update (continued)

vSS!ValidFrame	vRF!Header!NFIndicator	Update description
0	x	No valid frame received. – Message Buffer Data field not updated. – Frame Header field not updated. – Slot Status field updated. – DUP = 0 – DVAL <i>not</i> changed. – MBIF = 1, if the slot was not an empty dynamic slot. <i>Note: An empty dynamic slot is indicated by the following frame and slot status bit values:</i> vSS!ValidFrame = 0 and vSS!SyntaxError = 0 and vSS!ContentError = 0 and vSS!BViolation = 0.

Note: If the number of the last slot in the current communication cycle on a given channel is n , then all receive message buffers assigned to this channel with $FR_MBFIDRn[FID] > n$ will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in [Figure 1083](#).

Figure 1083. Message Reception timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following items:

- The message buffer segment that the message buffer is assigned to, as defined by the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#)
- The message buffer data field size, as defined by the related field of the [Message Buffer Data Size Register \(FR_MBDSR\)](#)
- The number of bytes received over the FlexRay bus

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than $2 \times FR_MBDSR.MBSEG1DS$, the CC writes only $2 \times FR_MBDSR.MBSEG1DS$ bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than $2 \times FR_MBDSR.MBSEG1DS$, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with $FR_MBDSR.MBSEG2DS$.

51.6.6.3.4 Received message access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in [Section 51.6.3.1, "Individual Message Buffers"](#).

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

51.6.6.3.5 Receive shadow buffer concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in [Section 51.6.3.2, "Receive shadow buffers"](#).

The receive shadow buffers temporarily store the received frame header and message data. The slot status information is generated after the slot boundary. If the slot status information indicates the reception of the valid non-null frame (see [Table 1089](#)), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the [Message Buffer Index Registers \(FR_MBIDX_{Rn}\)](#) with the content of the corresponding internal shadow buffer index register. In all other cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the [Message Buffer Index Registers \(FR_MBIDX_{Rn}\)](#). Instead, the index of the message buffer header field must be fetched from the [Message Buffer Index Registers \(FR_MBIDX_{Rn}\)](#).

51.6.7 Individual message buffer search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel whether a slot s in a communication cycle c is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm invoked at the following protocol-related events:

- NIT start
- Slot start in the static segment
- Minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot n searches for message buffers assigned or subscribed to slot $n + 1$.

In general, the message buffer search for the next slot n considers only message buffers that

1. Are enabled (that is, $\text{FR_MBCCSRn[EDS]} = 1$), and
2. Match the next slot n , (that is, $\text{FR_MBFIDRn[FID]} = n$)

On top of that, for the static segment, only those message buffers are considered that match the condition of at least one row of [Table 1090](#). For the dynamic segment, only those message buffers are considered that match the condition of at least one row of [Table 1091](#). These message buffers are called *matching* message buffers.

For each enabled channel, the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers, the message buffers with highest priority according to [Table 1090](#) for the static segment and according to [Table 1091](#) for the dynamic segment are selected.

Table 1090. Message buffer search priority (static segment)

Priority	MTD	LCKS	CMT	CCFM (1)	Description	Transition
(highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	1	—	0	1	Transmit buffer, matches cycle count, not committed	SA
	1	1	—	1	Transmit buffer, matches cycle count, locked	SA
2	1	—	—	—	Transmit buffer	SA
3	0	0	n/a	1	Receive buffer, matches cycle count, not locked	SB
(lowest) 4	0	1	n/a	1	Receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see [Section 51.6.7.1, "Message buffer cycle counter filtering"](#).

Table 1091. Message buffer search priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM (1)	Description	Transition
(highest) 0	1	0	1	1	Transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	Receive buffer, matches cycle count, not locked	SB
(lowest) 2	0	1	n/a	1	Receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see [Section 51.6.7.1, "Message buffer cycle counter filtering"](#)

If there are multiple message buffer with highest priority, the message buffer with the lowest message buffer number is selected. All message buffers that have the highest priority must have a consistent channel assignment as specified in [Section 51.6.7.2, "Message buffer channel assignment consistency"](#).

Depending on the message buffer channel assignment, the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in [Section 51.6.3.1, "Individual Message Buffers"](#).

51.6.7.1 Message buffer cycle counter filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the [Message Buffer Cycle Counter Filter Registers \(FR_MBCCFRn\)](#). This filter determines a set of communication cycles in which the message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled (CCFE = 0), this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

Equation 50 $MBCCFRn[CCFE] = 0$

Equation 51

$$CYCCNT \& MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \& MBCCFRn[CCFMSK]$$

51.6.7.2 Message buffer channel assignment consistency

The message buffer channel assignment given by the CHA and CHB bits in the [Message Buffer Cycle Counter Filter Registers \(FR_MBCCFRn\)](#) defines the channels on which the message buffer will receive or transmit. The message buffer with number n transmits or receives on channel A if $FR_MBCCFRn[CHA] = 1$ and transmits or receives on channel B if $FR_MBCCFRn[CHB] = 1$.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The behavior of the message buffer search is not defined if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in [Figure 1084](#).

Figure 1084. Inconsistent channel assignment

MB0	FR_MBFIDR0[FID] = 10	FR_MBCCFR0[CHA] = 1, FR_MBCCFR0[CHB] = 0	 single channel assignment
MB1	FR_MBFIDR1[FID] = 10	FR_MBCCFR1[CHA] = 1, FR_MBCCFR1[CHB] = 1	

51.6.7.3 Node-related slot multiplexing

The term *node-related slot multiplexing* applies to the dynamic segment only and refers to the functionality if transmit as well as receive message buffers are configured for the same slot.

According to [Table 1091](#) the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

51.6.7.4 Message buffer search error

There are two kinds of errors that may occur during message buffer search^(r).

51.6.7.4.1 Message buffer search start while running

If the message buffer search is running in slot $n - 1$ and the next message buffer search start event appears due to the start of slot n , the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the [CHI Error Flag Register \(FR_CHIERFR\)](#). As a result of this stop, no individual message buffer is identified for transmission or reception in slot n . Additionally, the search engine will not be started in slot n , and consequently no individual message buffer is identified for transmission or reception in slot $n + 1$.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency see [Section 51.7.5, "Number of usable message buffers"](#).

51.6.7.4.2 Illegal message buffer index found

If the message buffer search has finished the message buffer search in slot $n - 1$, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the [CHI Error Flag Register \(FR_CHIERFR\)](#) and no individual message buffer is identified for transmission or reception in slot n . The legal message buffer index values for the individual and receive shadow buffers are specified in [Section 51.5.2.52, "Receive Shadow Buffer Index Register \(FR_RSBR\)"](#) and [Section 51.5.2.82, "Message Buffer Index Registers \(FR_MBIDXRn\)"](#).

51.6.8 Individual message buffer reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on [Specific Configuration Data](#). The common configuration data given in the section on [Specific Configuration Data](#) can not be reconfigured when the protocol is out of the *POC:config* state.

51.6.8.1 Reconfiguration schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.

51.6.8.1.1 Basic type not changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSRn[MTD] is not changed. This type of reconfiguration is denoted by RC1 in [Figure 1085](#). Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

r. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to an search error, the received frame is considered for FIFO reception.

51.6.8.1.2 Buffer type not changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in [Figure 1085](#). It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

Figure 1085. Message buffer reconfiguration scheme

51.6.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

51.6.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. One FIFO is assigned to channel A, and the other FIFO is assigned to channel B. Both FIFOs work independently from each other.

The message buffer structure of each FIFO is described in [Section 51.6.3.3, "Receive FIFO"](#). The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- The FIFO system memory base address
- The index of the first FIFO entry given by the [Receive FIFO Start Index Register \(FR_RFSIR\)](#)
- The data field offset of the data field belonging to the first FIFO entry given by the [Receive FIFO Start Data Offset Register \(FR_RFSDOR\)](#)
- The number of FIFO entries and the length of each FIFO entry as given by the [Receive FIFO Depth and Size Register \(FR_RFDSR\)](#)

51.6.9.2 FIFO configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO Address Mode bit FAM in the [Module Configuration Register \(FR_MCR\)](#).

51.6.9.2.1 Single System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is the [System Memory Base Address Register \(FR_SYMBADR\)](#).

51.6.9.2.2 Dual System Memory Base Address mode

This mode is configured when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is the [Receive FIFO System Memory Base Address Register \(FR_RFSYMBADR\)](#).

The FIFO control and configuration data is given in [Section 51.6.3.7, "Receive FIFO control and configuration data"](#). The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details, see [Section 51.6.4, “FlexRay memory area layout”](#).

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

1. Configure the FIFO update and address modes in [Module Configuration Register \(FR_MCR\)](#).
2. Configure the FIFO system memory base address.
3. Configure the [Receive FIFO Start Index Register \(FR_RFSIR\)](#) with the first message buffer header index that belongs to the FIFO.
4. Configure the [Receive FIFO Start Data Offset Register \(FR_RFSDOR\)](#) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO.
5. Configure the [Receive FIFO Depth and Size Register \(FR_RFDSR\)](#) with FIFO entry size.
6. Configure the [Receive FIFO Depth and Size Register \(FR_RFDSR\)](#) with FIFO depth.
7. Configure the FIFO filters.

51.6.9.3 FIFO periodic timer

The FIFO periodic timer is used to generate a FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached but the FIFO is not empty. This can be used to prevent frames from getting stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the [Receive FIFO Periodic Timer Register \(FR_RFPTR\)](#). If the periodic timer duration `FR_RFPTR[PTD]` is configured to `0x0000`, the periodic timer is continuously expired. If the periodic timer duration `FR_RFPTR[PTD]` is configured to `0x3FFF`, the periodic timer never expires. If the periodic timer is configured to a value *ptd*, greater than `0x0000` and smaller `0x3FFF`, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

51.6.9.4 FIFO reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case, the FIFO filter path shown in [Figure 1086](#) is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the [Receive FIFO Fill Level and POP Count Register \(FR_RFFLPCR\)](#) is incremented. If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

51.6.9.5 FIFO almost-full interrupt generation

If the FIFO fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM (that is, $FLA > WM_A$ ($FLB > WM_B$)), then the FIFO almost-full interrupt flag $FR_GIFER[FAFAIF]$ ($FR_GIFER[FAFBIF]$) is asserted. If the periodic timer expires, and FIFOA (FIFOB) is not empty (that is, $FLA > 0$ ($FLB > 0$)), then the FIFO almost-full interrupt flag $FR_GIFER[FAFAIF]$ ($FR_GIFER[FAFBIF]$) is asserted.

51.6.9.6 FIFO overflow error generation

If the FIFOA (FIFOB) is full (that is, $FLA = FIFO_DEPTH_A$ ($FLB = FIFO_DEPTH_B$)) and the conditions for a FIFO reception as described in [Section 51.6.9.4, "FIFO reception"](#) are fulfilled, then the FIFO overflow error flag $FR_CHIERFR[FOVA_EF]$ ($FR_CHIERFR[FOVB_EF]$) is asserted.

51.6.9.7 FIFO message access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the [Receive FIFO Fill Level and POP Count Register \(\$FR_RFFLPCR\$ \)](#) is greater than 0. The [Receive FIFO A Read Index Register \(\$FR_RFARIR\$ \)](#) and the [Receive FIFO B Read Index Register \(\$FR_RFBIRIR\$ \)](#) point to a message buffer with valid content and the oldest frames stored in the FIFO. The respective read data field offsets can be calculated according to [Equation 1-125](#).

If the FIFO fill level FLA (FLB) in the [Receive FIFO Fill Level and POP Count Register \(\$FR_RFFLPCR\$ \)](#) is 0, then the FIFOA (FIFOB) contains no valid messages and the corresponding read index register [Receive FIFO A Read Index Register \(\$FR_RFARIR\$ \)](#) or [Receive FIFO B Read Index Register \(\$FR_RFBIRIR\$ \)](#) point to a message buffer with invalid content. In this case, the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the [Receive FIFO A Read Index Register \(\$FR_RFARIR\$ \)](#) ([Receive FIFO B Read Index Register \(\$FR_RFBIRIR\$ \)](#)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to [Equation 1-125](#). The application can access the message data as described in [Section 51.6.3.3, "Receive FIFO"](#). When the application has read the message buffer data and status information, it can update the FIFO as described in [Section 51.6.9.8, "FIFO update"](#).

51.6.9.8 FIFO update

The application updates the FIFOA (FIFOB) by writing a pop count value pc different from 0 to the PCA (PCB) field in the [Receive FIFO Fill Level and POP Count Register \(\$FR_RFFLPCR\$ \)](#).

As a result of this operation, the CC removes the oldest pc entries from FIFOA (FIFOB).

If the specified pop count value pc is greater than the current fill level fl provided in FLA (FAB) field, then only fl entries are removed from the FIFOA (FIFOB), the remaining $fl - pc$ requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the [Receive FIFO A Read Index Register \(\$FR_RFARIR\$ \)](#) ([Receive FIFO B Read Index Register \(\$FR_RFBIRIR\$ \)](#)) is incremented by the number of removed items. If the

read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in [Receive FIFO Start Index Register \(FR_RFSIR\)](#) automatically.

51.6.9.8.1 FIFO interrupt flag update

The FIFO Interrupt Flag Update mode is configured when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode, FIFOA (FIFOB) will be updated by one entry when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the [Receive FIFO A Read Index Register \(FR_RFARIR\)](#) ([Receive FIFO B Read Index Register \(FR_RFBIRIR\)](#)) is incremented by 1 if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

51.6.9.9 FIFO filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides three sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in [Figure 1086](#).

Figure 1086. Received frame FIFO filter path

A received frame passes the FIFO filtering if it has passed all three type of filter.

51.6.9.9.1 RX FIFO Frame ID Value-mask Rejection filter

The Frame ID Value-mask Rejection filter is a value-mask filter and is defined by the fields in the [Receive FIFO Frame ID Rejection Filter Value Register \(FR_RFFIDRFVR\)](#) and the [Receive FIFO Frame ID Rejection Filter Mask Register \(FR_RFFIDRFMR\)](#). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter (that is, it is not rejected).

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-mask Rejection filter if [Equation 52](#) is fulfilled.

Equation 52

$$\begin{aligned} & \text{FID} \& \text{FR_RFFIDRFMR}[\text{FIDRFMSK}] \neq \\ & \neq \text{FR_RFFIDRFVR}[\text{FIDRFVAL}] \& \text{FR_RFFIDRFMR}[\text{FIDRFMSK}] \end{aligned}$$

The RX FIFO Frame ID Value-mask Rejection filter can be configured to pass all frames by using the following settings:

- $\text{FR_RFFIDRFVR}[\text{FIDRFVAL}] = 0x000$ and $\text{FR_RFFIDRFMR}[\text{FIDRFMSK}] = 0x7FF$

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-mask Rejection filter can be configured to reject all frames by using the following settings:

- $\text{FR_RFFIDRFMR}[\text{FIDRFMSK}] = 0x000$

Using the settings above, [Equation 52](#) can never be fulfilled ($0 \neq 0$) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

51.6.9.9.2 RX FIFO Frame ID Range Rejection filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the [Receive FIFO Range Filter Configuration Register \(FR_RFRFCFR\)](#) and controlled by the [Receive FIFO Range Filter Control Register \(FR_RFRFCTR\)](#). The RX FIFO frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range Rejection filters if either no rejection filter is enabled, or, if for all of the enabled RX FIFO Frame ID Range Rejection filters (that is, $\text{FR_RFRFCTR}[\text{FiMD}] = 1$ and $\text{FR_RFRFCTR}[\text{FiEN}] = 1$), [Equation 53](#) is fulfilled.

Equation 53

$$(\text{FID} < \text{FR_RFRFCFR}_{\text{SEL}}[\text{SID}_{\text{IBD}} = 0]) \text{ or } (\text{FR_RFRFCFR}_{\text{SEL}}[\text{SID}_{\text{IBD}} = 1] < \text{FID})$$

Consequently, all frames with a frame ID that fulfills [Equation 54](#) for at least one of the enabled rejection filters will be rejected and thus not pass.

Equation 54

$$\text{FR_RFRFCFR}_{\text{SEL}}[\text{SID}_{\text{IBD}} = 0] \leq \text{FID} \leq \text{FR_RFRFCFR}_{\text{SEL}}[\text{SID}_{\text{IBD}} = 1]$$

51.6.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the [Receive FIFO Range Filter Configuration Register](#)

(*FR_RFRFCFR*) and controlled by the *Receive FIFO Range Filter Control Register (FR_RFRFCTR)*. The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, if for at least one of the enabled RX FIFO Frame ID Range acceptance filters (that is, $FR_RFRFCTR[FIMD] = 0$ and $FR_RFRFCTR[FIEN] = 1$), *Equation 55* is fulfilled.

Equation 55

$$FR_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR_RFRFCFR_{SEL}[SID_{IBD=1}]$$

51.6.9.9.4 RX FIFO Message ID Acceptance filter

The RX FIFO Message ID Acceptance filter is a value-mask filter and is defined by the *Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)* and the *Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)*. This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance filter if *Equation 56* is fulfilled.

Equation 56

$$\begin{aligned} MID \& FR_RFMIDAFMR[MIDAFMSK] = \\ &= FR_RFMIDAFMR[MIDAFVAL] \& FR_RFMIDAFMR[MIDAFMSK] \end{aligned}$$

The RX FIFO Message ID Acceptance filter can be configured to accept all frames by setting

- $FR_RFMIDAFMR[MIDAFMSK] := 0x000$

Using the settings above, *Equation 56* is always fulfilled and all frames will pass.

51.6.10 Channel device modes

This section describes the two FlexRay channel device modes that are supported by the CC.

51.6.10.1 Dual-Channel Device mode

In Dual-Channel Device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX , FR_A_TX , and $FR_A_TX_EN$ is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX , FR_B_TX , and $FR_B_TX_EN$ is connected to the physical bus channel B. The dual-channel system is shown in *Figure 1087*.

Figure 1087. Dual-Channel Device mode

51.6.10.2 Single-Channel Device mode

Single-Channel Device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals `FR_A_RX`, `FR_A_TX`, and `FR_A_TX_EN` and can be connected to either the physical bus channel A (shown in [Figure 1088](#)) or the physical bus channel B (shown in [Figure 1089](#)).

If the device is configured as a single-channel device by setting `FR_MCR[SCM]` to 1, only the internal channel A and FlexRay port A are used. Depending on the setting of `FR_MCR[CHA]` and `FR_MCR[CHB]`, the internal channel A behaves either as a FlexRay channel A or FlexRay channel B. The bit `FR_MCR[CHA]` must be set, if FlexRay port A is connected to FlexRay channel A. The bit `FR_MCR[CHB]` must be set if FlexRay port A is connected to FlexRay channel B. The two FlexRay channels differ only in the initial value for the frame CRC `cCrclnit`. For a single-channel device, the application can access and configure only the registers related to internal channel A.

Figure 1088. Single-Channel Device mode (channel A)

Figure 1089. Single-Channel Device mode (channel B)

51.6.11 External clock synchronization

The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the [Protocol Operation Control Register \(FR_POCR\)](#). The PE applies the external correction values in the next even-odd cycle pair as shown in [Figure 1090](#) and [Figure 1091](#).

Note: The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle $2n + 1$ will be affected by the external offset correction, the EOC_AP field must be written to after the start of cycle $2n$ and before the end

of the static segment of cycle $2n + 1$. If this field is written to after the end of the static segment of cycle $2n + 1$, it is not guaranteed that the external correction value is applied in cycle $2n + 1$. If the value is not applied in cycle $2n + 1$, then the value will be applied in the cycle $2n+3$. Refer to [Figure 1090](#) for timing details.

Figure 1090. External offset correction write and application timing

If the rate correction for the cycle pair $[2n + 2, 2n + 3]$ will be affected by the external offset correction, the ERC_AP field must be written to after the start of cycle $2n$ and before the end of the static segment of cycle $2n + 1$. If this field is written to after the end of the static segment of cycle $2n + 1$, it is not guaranteed that the external correction value is applied in cycle pair $[2n + 2, 2n + 3]$. If the value is not applied for cycle pair $[2n + 2, 2n + 3]$, then the value will be applied for cycle pair $[2n+4, 2n+5]$. Refer to [Figure 1091](#) for details.

Figure 1091. External rate correction write and application timing

51.6.12 Sync frame ID and sync frame deviation tables

The FlexRay protocol requires the provision of a snapshot of the synchronization frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note: Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.

51.6.12.1 Sync frame ID table content

The sync frame ID table is a snapshot of the protocol-related variables [vsSyncIdListA](#) and [vsSyncIdListB](#) for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

51.6.12.2 Sync frame deviation table content

The sync frame deviation table is a snapshot of the protocol-related variable `zsDev(id)(oe)(ch)!Value`. Each sync frame deviation table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the sync frame ID table.

Figure 1092. Sync table memory layout

51.6.12.3 Sync frame ID and sync frame deviation table setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in [Figure 1092](#). Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the [Sync Frame Table Offset Register \(FR_SFTOR\)](#).

51.6.12.4 Sync frame ID and sync frame deviation table generation

The application controls the generation process of the sync frame ID and sync frame deviation tables into the FlexRay memory area using the [Sync Frame Table Configuration, Control, Status Register \(FR_SFTCCSR\)](#). A summary of the copy modes is given in [Table 1092](#).

Table 1092. Sync frame table generation modes

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No sync frame table copy
0	0	1	Sync frame ID tables will be copied continuously
0	1	0	Reserved

Table 1092. Sync frame table generation modes (continued)

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	1	1	Sync frame ID tables and sync frame deviation tables will be copied continuously
1	0	0	No sync frame table copy
1	0	1	Sync frame ID tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync frame ID tables and sync frame deviation tables for next even-odd-cycle pair will be copied

The sync frame table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even-cycle-related tables after the start of the NIT of the next even cycle. The CC checks whether the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. When all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the [Protocol Interrupt Flag Register 1 \(FR_PIFR1\)](#). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.

To read the generated tables, the application must lock the tables to prevent the CC from updating them. The locking is initiated by writing a 1 to the Even Table Lock trigger, FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding status information fields, SFRA and SFRB, in the [Sync Frame Counter Register \(FR_SFCNTR\)](#). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in [Figure 1092](#).

After reading all the data from the locked tables, the application must unlock the table by writing to the Even Table Lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the [Sync Frame Counter Register \(FR_SFCNTR\)](#) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the [Sync Frame Counter Register \(FR_SFCNTR\)](#).

Figure 1093. Sync frame table trigger and generation timing

51.6.12.5 Sync frame table access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in [Figure 1092](#). During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

51.6.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the [Sync Frame Table Configuration, Control, Status Register \(FR_SFTCCSR\)](#). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

51.6.13 MTS generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol (MTS) in the symbol window on channel A or channel B.

The application can configure the set of communication cycles that transmit the MTS over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the [MTS A Configuration Register \(FR_MTSACFR\)](#) and [MTS B Configuration Register \(FR_MTSBCFR\)](#).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the [MTS A Configuration Register \(FR_MTSACFR\)](#) or [MTS B Configuration Register \(FR_MTSBCFR\)](#). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT if [Equation 57](#), [Equation 58](#), and [Equation 59](#) are fulfilled.

$$\text{Equation 57} \quad \text{FR_PSR0[PROTSTATE]} = \text{POC:normal active}$$

$$\text{Equation 58} \quad \text{FR_MTSACRF[MTE]} = 1$$

$$\begin{aligned} \text{Equation 59} \quad & \text{CYCCNT} \& \text{FR_MTSACFR[CYCCNTMSK]} = \\ & = \text{FR_MTSACFR[CYCCNTVAL]} \& \text{FR_MTSACFR[CYCCNTMSK]} \end{aligned}$$

The MTS is transmitted over channel B in the communication cycle with number CYCCNT if [Equation 57](#), [Equation 60](#) and [Equation 61](#) are fulfilled.

Equation 60 $FR_MTSBCRF[MTE] = 1$

Equation 61 $CYCCNT \& FR_MTSBCFR[CYCCNTMSK] = FR_MTSBCFR[CYCCNTVAL] \& FR_MTSBCFR[CYCCNTMSK]$

51.6.14 Key slot transmission

51.6.14.1 Key slot assignment

A key slot is assigned to the CC if the key_slot_id field in the [Protocol Configuration Register 18 \(FR_PCR18\)](#) is configured with a value greater than 0 and less than or equal to number_of_static_slots in [Protocol Configuration Register 2 \(FR_PCR2\)](#); otherwise no key slot is assigned.

51.6.14.2 Key slot transmission in *POC:startup*

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by [FlexRay Communications System Protocol Specification, Version 2.1 Rev A](#).

51.6.14.3 Key slot transmission in *POC:normal active*

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in [Table 1093](#) is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see [Section 51.6.6.2.5, "Message transmission"](#)). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see [Section 51.6.6.2.6, "Null frame transmission"](#)).

Table 1093. Key slot frame type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	Normal frame
0	1	Normal frame ⁽¹⁾
1	0	Sync frame
1	1	Startup frame

1. The frame transmitted has a semantically incorrect header and will be detected as an invalid frame at the receiver.

51.6.15 Sync frame filtering

Each received synchronization frame must pass the Sync Frame Acceptance filter and the Sync Frame Rejection filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled (that is, the SFFE control bit in the [Module Configuration Register \(FR_MCR\)](#) is cleared), all received synchronization frames are considered for clock synchronization. If a received synchronization frame did not pass at least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

51.6.15.1 Sync frame acceptance filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the [Sync Frame ID Acceptance Filter Value Register \(FR_SFIDAFVR\)](#) and the mask is configured in the [Sync Frame ID Acceptance Filter Mask Register \(FR_SFIDAFMR\)](#). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if [Equation 62](#) or [Equation 63](#) evaluates to true.

Equation 62 $FR_MCR[SFFE] = 0$

Equation 63

$$FID \& FR_SFIDAFMR[FMSK] = \\ = FR_SFIDAFVR[FVAL] \& FR_SFIDAFMR[FMSK]$$

Note: Sync frames are transmitted in the static segment only. Thus $FID \leq 1023$.

51.6.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the [Sync Frame ID Rejection Filter Register \(FR_SFIDRFR\)](#). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if [Equation 64](#) or [Equation 65](#) evaluates to true.

Equation 64 $FR_MCR[SFFE] = 0$

Equation 65 $FID \neq FR_SFIDRFR[SYNFRID]$

Note: Sync frames are transmitted in the static segment only. Thus $FID \leq 1023$.

51.6.16 Strobe signal support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in [Table 980](#).

51.6.16.1 Strobe signal assignment

Each of the strobe signals listed in [Table 980](#) can be assigned to one of the four strobe ports using the [Strobe Signal Control Register \(FR_STBSCR\)](#). To assign multiple strobe signals, the application must write multiple times to the [Strobe Signal Control Register \(FR_STBSCR\)](#) with appropriate settings.

To read out the current settings for a strobe signal with number n , the application must execute the following sequence.

1. Write to FR_STBSCR with WMD = 1 and SEL = n . (Updates the SEL field only.)
2. Read STBCSR.
The SEL field provides n and the ENB and STBPSEL fields provides the settings for signal n .

51.6.16.2 Strobe signal timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.

The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay bus. These signals are listed in [Table 980](#) with a negative clock offset. An example waveform is given in [Figure 1094](#).

Figure 1094. Strobe signal timing (type = pulse, clk_offset = -2)

Other signals refer to events that occurred on the FlexRay bus some cycles before the strobe signal is changed. These signals are listed in [Table 980](#) with a positive clock offset. An example waveform is given in [Figure 1095](#).

Figure 1095. Strobe signal timing (type = pulse, clk_offset = +4)

51.6.17 Timer support

The CC provides two timers that run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In Non-repetitive mode, the timer stops if it expires. In Repetitive mode, the timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

51.6.17.1 Absolute timer T1

Absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the [Protocol Interrupt Flag Register 0 \(FR_PIFR0\)](#) is set at the macrotick start event, if [Equation 66](#) and [Equation 67](#) are fulfilled.

Equation 66

$$\begin{aligned} & \text{CYCTR}[\text{CTCNT}] \& \text{FR_TI1CYSR}[\text{T1_CYC_MSK}] = \\ & = \text{FR_TI1CYSR}[\text{T1_CYC_VAL}] \& \text{FR_TI1CYSR}[\text{T1_CYC_MSK}] \end{aligned}$$

Equation 67
$$\text{FR_MTCTR}[\text{MTCT}] = \text{FR_TI1MTOR}[\text{T1_MTOFFSET}]$$

If the timer 1 interrupt enable bit `TI1_IE` in the [Protocol Interrupt Enable Register 0 \(FR_PIER0\)](#) is asserted, an interrupt request is generated.

The status bit `T1ST` is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the `T1ST` bit is not cleared and the timer is restarted immediately. The `T1ST` is cleared when the timer is stopped.

The corresponding interrupt condition (that is, when [Equation 66](#) and [Equation 67](#) are fulfilled) also leads to an event-out indication on an output port (`fr_evt_tim1`) based on the `[TIM1_EE]` bit of the [Protocol Event Output Enable and StopWatch Control Register \(FR_PEOER\)](#).

51.6.17.2 Absolute/relative timer T2

Timer T2 can be configured to be an absolute or relative timer by setting the `T2_CFG` control bit in the [Timer Configuration and Control Register \(FR_TICCR\)](#). The status bit `T2ST` is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the `T2ST` bit is not cleared and the timer is restarted immediately. The `T2ST` is cleared when the timer is stopped.

51.6.17.2.1 Absolute timer T2

If timer T2 is configured as an absolute timer, it has the same functionality as timer T1 but the configuration from [Timer 2 Configuration Register 0 \(FR_TI2CR0\)](#) and [Timer 2 Configuration Register 1 \(FR_TI2CR1\)](#) is used. When timer T2 expires, the interrupt flag `TI2_IF` in the [Protocol Interrupt Flag Register 0 \(FR_PIFR0\)](#) is set. If the timer 1 interrupt enable bit `TI1_IE` in the [Protocol Interrupt Enable Register 0 \(FR_PIER0\)](#) is asserted, an interrupt request is generated.

The corresponding interrupt condition for T2 also leads to an event out indication on an output port (`fr_evt_tim2`) based on the `[TIM2_EE]` bit of the [Protocol Event Output Enable and StopWatch Control Register \(FR_PEOER\)](#).

51.6.17.2.2 Relative Timer T2

If timer T2 is configured as a relative timer, the interrupt flag `TI2_IF` in the [Protocol Interrupt Flag Register 0 \(FR_PIFR0\)](#) is set when the programmed amount of macroticks `MT[31:0]`—defined by [Timer 2 Configuration Register 0 \(FR_TI2CR0\)](#) and [Timer 2 Configuration Register 1 \(FR_TI2CR1\)](#)—has elapsed since the trigger or restart of timer T2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of `MT[31:0]` is checked and then decremented. Thus, if the timer is started with `MT[31:0] == 0`, it expires at the next macrotick start. The corresponding interrupt condition for T2 also leads to an event out indication on an output port (`fr_evt_tim2`) based on the `[TIM2_EE]` bit of the [Protocol Event Output Enable and StopWatch Control Register \(FR_PEOER\)](#).

51.6.18 Slot status monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per-channel base. The content of the slot status vector is described in [Table 1094](#). The PE provides the

slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in [Figure 1096](#).

Figure 1096. Slot status vector update

Note: The slot status for the NIT of cycle n is provided after the start of cycle $n+1$.

Table 1094. Slot status content

	Status content
static / dynamic Slot	Slot-related status vSS!ValidFrame—valid frame received vSS!SyntaxError—syntax error occurred while receiving vSS!ContentError—content error occurred while receiving vSS!BViolation—boundary violation while receiving for slots in which the module transmits: vSS!TxConflict—reception ongoing while transmission starts for slots in which the module does not transmit: vSS!TxConflict—reception ongoing while transmission starts first valid - channel that has received the first valid frame Received-frame-related status extracted from a) header of valid frame, if vSS!ValidFrame = 1 b) last received header, if vSS!ValidFrame = 0 c) set to 0, if nothing was received vRF!Header!NFIndicator—null frame indicator (0 for null frame) vRF!Header!SuFIndicator—startup frame indicator vRF!Header!SyFIndicator—sync frame indicator

Table 1094. Slot status content (continued)

	Status content
Symbol window	Window-related status <i>vSS!ValidFrame</i> —always 0 <i>vSS!ContentError</i> —content error occurred while receiving <i>vSS!SyntaxError</i> —syntax error occurred while receiving <i>vSS!BViolation</i> —boundary violation while receiving <i>vSS!TxConflict</i> —reception ongoing while transmission starts Received-symbol-related status <i>vSS!ValidMTS</i> —valid Media Test Access Symbol received Received-frame-related status see static/dynamic slot
NIT	NIT-related status <i>vSS!ValidFrame</i> —always 0 <i>vSS!ContentError</i> —content error occurred while receiving <i>vSS!SyntaxError</i> —syntax error occurred while receiving <i>vSS!BViolation</i> —boundary violation while receiving <i>vSS!TxConflict</i> —always 0 Received-frame-related status see static/dynamic slot

51.6.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, *Channel A Status Error Counter Register (FR_CASERCR)* and *Channel B Status Error Counter Register (FR_CBSECR)* are incremented by one if at least one of four slot status error bits, *vSS!SyntaxError*, *vSS!ContentError*, *vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap around after they have reached the maximum value.

51.6.18.2 Protocol Status Registers

The *Protocol Status Register 2 (FR_PSR2)* provides slot status information about the NIT and the symbol window. The *Protocol Status Register 3 (FR_PSR3)* provides aggregated slot status information.

51.6.18.3 Slot Status Registers

The eight slot status registers, *Slot Status Registers (FR_SSR0–FR_SSR7)*, can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status-related and received frame/symbol-related status information, as given in *Table 1094*, except for the *first valid* indicator for non-transmission slots.

51.6.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, *Slot Status Counter Registers (FR_SSCR0–FR_SSCR3)*. Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the *Slot Status*

Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in [Figure 1097](#).

Figure 1097. Slot status counting and FR_SSCCRn update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCCRn register reflects, in cycle n , the status of the NIT of cycle $n - 2$, and the status of all static slots and the symbol window of cycle $n - 1$.

The increment condition for each slot status counter consists of two parts: the frame-related condition part and the slot-related condition part. The internal slot status counter FR_SSCCRn_INT is incremented if at least one of the following conditions is fulfilled:

1. Frame-related condition:

- $(\text{FR_SSCCRn}[\text{VFR}] \mid \text{FR_SSCCRn}[\text{SYF}] \mid \text{FR_SSCCRn}[\text{NUF}] \mid \text{FR_SSCCRn}[\text{SUF}]) \parallel$
count on frame condition
= 1;

and

- $(\sim \text{FR_SSCCRn}[\text{VFR}] \mid \text{vSS!ValidFrame}) \& \parallel$ valid frame restriction
 $(\sim \text{FR_SSCCRn}[\text{SYF}] \mid \text{vRF!Header!SyFIndicator}) \& \parallel$ sync frame indicator restriction
 $(\sim \text{FR_SSCCRn}[\text{NUF}] \mid \sim \text{vRF!Header!NFIndicator}) \& \parallel$ null frame indicator restriction
 $(\sim \text{FR_SSCCRn}[\text{SUF}] \mid \text{vRF!Header!SuFIndicator}) \parallel$ startup frame indicator restriction
= 1;

Note: The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus, the VFR must always be set whenever the count-on-frame condition is used.

2. Slot-related condition:

- $(\text{FR_SSCCRn}[\text{STATUSMASK}[3]] \& \text{vSS!ContentError}) \parallel$ increment on content error
 $(\text{FR_SSCCRn}[\text{STATUSMASK}[2]] \& \text{vSS!SyntaxError}) \parallel$ increment on syntax error
 $(\text{FR_SSCCRn}[\text{STATUSMASK}[1]] \& \text{vSS!BViolation}) \parallel$ increment on boundary violation
 $(\text{FR_SSCCRn}[\text{STATUSMASK}[0]] \& \text{vSS!TxConflict}) \parallel$ increment on transmission conflict
= 1;

If the slot status counter is in Single-cycle mode (that is, FR_SSCCRn[MCY] = 0), the internal slot status counter FR_SSCCRn_INT is reset at each cycle start. If the slot status

counter is in Multicycle mode (that is, $FR_SSCCRn[MCY] = 1$), the counter is not reset and incremented until the maximum value is reached.

51.6.18.5 Message Buffer Slot Status field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in [Table 1094](#) for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update sections in [Section 51.6.3.4.1, Individual message buffer configuration data](#).

51.6.19 System bus access

This section provides a description of the system bus access failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in [Section 51.6.19.1, "System bus access failure types"](#).

The behavior of the CC after the occurrence of a system bus access failure is described in [Section 51.6.19.2, "System bus access failure response"](#).

51.6.19.1 System bus access failure types

This section describes the two types of system bus access failures.

51.6.19.1.1 System bus illegal address access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions that are treated as a system bus illegal address access:

- The system bus subsystem detects a CC access to an illegal system memory address.
- The CC detects the usage of a data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see [Section 51.6.24.3.1, "CHI LRAM error response after CC read"](#)).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the [CHI Error Flag Register \(FR_CHIERFR\)](#).

51.6.19.1.2 System bus access timeout

A system bus access timeout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see [Section 51.7.1.1, "Configure System Memory Access Timeout Register \(FR_SYMATOR\)"](#)).

If a system bus access timeout is detected, the CC sets the SBCF_EF flag in the [CHI Error Flag Register \(FR_CHIERFR\)](#).

51.6.19.2 System bus access failure response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the [Module Configuration Register \(FR_MCR\)](#).

51.6.19.2.1 Continue after system bus access failure

If FR_MCR[SBFF] is 0, the CC will continue its operation after the occurrence of the system bus access failure, but it will not generate any system bus accesses until the start of the next communication cycle. Since no data is read from or written to the FlexRay memory area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated in which the remaining header and frame data are replaced by all zeros. Depending on the point in time, this can affect the PPI bit, the header CRC, the payload length in the case of a dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted or received, except for the key slot; a sync or startup null-frame is transmitted if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

51.6.19.2.2 Freeze after system bus access failure

If FR_MCR[SBFF] is set to 1, the CC will go into Freeze mode immediately after the occurrence of one of the system bus access failures.

51.6.20 Interrupt support

The CC provides 172 individual interrupt sources and five combined interrupt sources.

51.6.20.1 Individual interrupt sources

51.6.20.1.1 Message buffer interrupts

The CC provides 128 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSRn[MBIF] and an interrupt enable bit FR_MBCCSRn[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

51.6.20.1.2 FIFO interrupts

The CC provides two FIFO interrupt sources.

Each of the two FIFOs provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the [Global Interrupt Flag and Enable Register \(FR_GIFER\)](#) if the corresponding receive FIFO fill level exceeds the defined watermark.

51.6.20.1.3 Wakeup interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

51.6.20.1.4 Protocol interrupts

The CC provides 25 interrupt sources for protocol-related events. For details, see the [Protocol Interrupt Flag Register 0 \(FR_PIFR0\)](#) and [Protocol Interrupt Flag Register 1 \(FR_PIFR1\)](#). Each interrupt source has its own interrupt enable bit.

51.6.20.1.5 CHI interrupts

The CC provides 16 interrupt sources for CHI-related error events. For details, see the [CHI Error Flag Register \(FR_CHIERFR\)](#). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

51.6.20.2 Combined interrupt sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

51.6.20.2.1 Receive message buffer interrupt

The receive message buffer interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

51.6.20.2.2 Transmit message buffer interrupt

The transmit message buffer interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

51.6.20.2.3 Protocol interrupt

The protocol interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set..

51.6.20.2.4 CHI interrupt

The CHI interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

51.6.20.2.5 Module interrupt

The module interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

Figure 1098. .Scheme of FR_GIFER interrupt signal generation

Figure 1099. FR_EEIFER interrupt signal generation scheme

Figure 1100. FR_CIFR flag generation scheme

51.6.21 Lower bit rate support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset*. The application configures the FlexRay channel bit rate by setting the BITRATE field in the *Module Configuration Register (FR_MCR)*. The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings, and the related protocol parameter values are shown in *Table 1095*.

Table 1095. FlexRay channel bit rate control

FlexRay channel bit rate [Mbit/s]	FR_MCR[BITRATE]	<i>pdMicrotick</i> [ns]	<i>gdSampleClockPeriod</i> [ns]	pSamplesPerMicrotick	cSamplesPerBit	cStrobeOffset
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note: The bit rate of 8 Mbit/s is not defined by the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

51.6.22 PE data memory (PE DRAM)

The PE data memory (PE DRAM) is 128 word, 16-bit wide memory with byte access that contains the program data of the PE internal CPU. The PE DRAM is divided into two banks of 8 bits each. The memory data [7:0] is assigned to BANK0 and the memory data [15:8] is assigned to BANK1.

Table 1096. PE DRAM layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
...		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via [PE DRAM Access Register \(FR_PEDRAR\)](#) and [PE DRAM Access Register \(FR_PEDRAR\)](#). This functionality is used to check the memory error detection.

51.6.22.1 PE DRAM read access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;
// INST=0x5; ADDR=070
2. Wait until FR_PEDRAR[DAD] == 1;
// wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA];
// read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause a response delay with a maximum of 1000 PE clock cycle (25 µs).

51.6.22.2 PE DRAM write access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;
// write value to be written into data register
2. FR_PEDRAR:= 0x30E0;
// INST=0x3; ADDR=0x70
3. wait until FR_PEDRAR[DAD] == 1;
// wait for end of PE DRAM access
4. val = FR_PEDRDR[DATA];
// read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25 µs).

If the conditions given in [Section 51.6.22.3, “PE DRAM write access limitations](#) are fulfilled, the data provided in [PE DRAM Access Register \(FR_PEDRAR\)](#) is written into the PE DRAM, read back in the next clock cycle, and stored into the [PE DRAM Access Register \(FR_PEDRAR\)](#). Otherwise, data is not written into the PE DRAM and 0x0000 is stored into the [PE DRAM Access Register \(FR_PEDRAR\)](#).

51.6.22.3 PE DRAM write access limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not in *POC:default config* state, only PE DRAM address 0x70 is writable.

51.6.23 CHI lookup-table memory (CHI LRAM)

The CHI lookup-table memory (CHI LRAM) is an CHI-internal memory that contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or six data field offsets are contained in one memory row. The CHI LRAM is divided into six memory banks.

Table 1097. CHI LRAM layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
...						
0x3F	FR_MBIDXR127	FR_MBFIDR127	FR_MBCCFR127	FR_MBIDXR126	FR_MBFIDR126	FR_MBCCFR126
0x40	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
...						
0x55	FR_MBDOR131	FR_MBDOR130	FR_MBDOR129	FR_MBDOR128	FR_MBDOR127	FR_MBDOR126
0x56	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

51.6.23.1 CHI LRAM read and write access

The CHI LRAM is accessed by the application via regular register read and write accesses.

51.6.24 Memory content error detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses a standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDED). The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SEDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

51.6.24.1 Memory error types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as a special case. The FlexRay module detects and indicates the memory errors as shown in [Table 1098](#). The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error-free bank has been read.

Table 1098. Detected memory error types

Memory	Priority	Memory data	Indication
CHI LRAM	0 (highest)	All zeros	Non-corrected error
PE DRAM			Non-corrected error
CHI LRAM		All ones	Non-corrected error
PE DRAM			Non-corrected error
CHI LRAM	1 (lowest)	One bit flipped	Non-corrected error
PE DRAM			Corrected error
CHI LRAM		Two bits flipped	Non-corrected error
PE DRAM			Non-corrected error
CHI LRAM		Three or more bits flipped	One out of {no error, non-corrected error}, defined by coding given in Section 51.6.24.2.3: CHI LRAM checkbits and Section 51.6.24.2.4: CHI LRAM syndrome
PE DRAM			One out of {no error, corrected error, non-corrected error}, defined by coding given in Section 51.6.24.2.1: PE DRAM checkbits and Section 51.6.24.2.2: PE DRAM syndrome

51.6.24.2 Memory error reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the [Module Configuration Register \(FR_MCR\)](#) is set.

For each of the two memories, there are two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the [ECC Error Interrupt Flag and Enable Register \(FR_EEIFER\)](#) is set.

- If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.
- If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to the above, the error indications (corrected/non-corrected) along with the failing address are sent out from the module for external error logging and corrective actions by the software.

51.6.24.2.1 PE DRAM checkbits

The coding of the checkbits reported in [ECC Error Report Code Register \(FR_EECCR\)](#) for PE DRAM memory errors is shown in [Table 1098](#). This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 1099. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4 ⁽¹⁾	X	X	X	X	X	X	X	X	X	X	X	X
3 ⁽²⁾	—	—	—	—	X	X	X	X	—	—	—	—
2	—	—	—	—	X	—	—	—	X	X	X	—
1	—	—	—	—	—	X	X	—	X	X	—	X
0	—	—	—	—	—	X	—	X	X	—	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is an even number of 1's in columns with X.

2. The checkbits CODE[3]... CODE[0] are set to 1 if and only if there is an odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFF are valid code words written into the memory.

51.6.24.2.2 PE DRAM syndrome

The coding of the syndrome reported in the [ECC Error Report Code Register \(FR_EERCRCR\)](#) for PE DRAM memory errors is shown in [Table 1100](#).

Table 1100. FR_EERCRCR[CODE] PE DRAM syndrome coding

FR_EERCRCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data != 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected error (parity bit 0)
0x0	0x2	Corrected error (parity bit 1)
0x0	0x3	Corrected error (data bit 0)
0x0	0x4	Corrected error (parity bit 2)
0x0	0x5	Corrected error (data bit 1)
0x0	0x6	Corrected error (data bit 2)
0x0	0x7	Corrected error (data bit 3)
0x0	0x8	Corrected error (parity bit 3)
0x0	0x9	Corrected error (data bit 4)
0x0	0xA	Corrected error (data bit 5)
0x0	0xB	Corrected error (data bit 6)
0x0	0xC	Corrected error (data bit 7)
0x0	0xD–0xF	Non-corrected error
0x1	0x1–0xF	Non-corrected error

51.6.24.2.3 CHI LRAM checkbits

The coding of the checkbits reported in [ECC Error Report Code Register \(FR_EECCR\)](#) for CHI LRAM memory errors is shown in [Table 1101](#). This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 1101. CHI LRAM checkbits coding

CODE ⁽¹⁾	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	—	—	—	—	—	—	—	—	—	—	—
3	—	—	—	—	—	X	X	X	X	X	X	X	—	—	—	—
2	X	X	—	—	—	X	X	X	X	—	—	—	X	X	X	—
1	—	—	X	X	—	X	X	—	—	X	X	—	X	X	—	X
0	X	—	X	—	X	X	—	X	—	X	—	X	X	—	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is an odd number of 1's in all columns with X.

51.6.24.2.4 CHI LRAM syndrome

The coding of the syndrome reported in [ECC Error Report Code Register \(FR_EECCR\)](#) for CHI LRAM memory errors is shown in [Table 1102](#).

Table 1102. FR_EECCR[CODE] CHI LRAM syndrome coding

FR_EECCR[CODE]	Description
0x00	No Error (never appears in error report registers)
0x01–0x1F	Non-corrected error

51.6.24.3 Memory error response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the [Module Configuration Register \(FR_MCR\)](#) is set.

In case a *corrected* memory error is detected, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

51.6.24.3.1 CHI LRAM error response after CC read

When the CC is out of the [POC:default config](#) state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access, the error response of the module depends from LRAM location where the error occurred.

- If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current

search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.

If the affected message buffer is a Tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is an Rx message buffer, no frame will be received to this message buffer in the next slot.

- If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx, the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs with respect to payload access for the complete frame.

51.6.24.3.2 CHI LRAM error response after application read

The application can read the content of the CHI LRAM by reading the FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn, FR_MBDORn, and FR_LEETRn registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read, and continues its normal operation.

51.6.24.3.3 PE DRAM error response after CC read

If the CC detects a non-corrected memory error during an internal read of program data contained in PE DRAM, this is considered a fatal protocol error and the module enters the protocol freeze state immediately.

51.6.24.3.4 PE DRAM error response after application read in *POC:default config* state

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered a fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

51.6.24.3.5 PE DRAM error response after application read out of *POC:default config*

If the CC detects a non-corrected memory error during an application-triggered read from any PE DRAM address and the protocol is not in the *POC:default config* state, this error is not considered a fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

51.6.25 Memory error injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the *Module Configuration Register (FR_MCR)* and the error injection enable control bit EIE in the *ECC Error Report and Injection Control Register (FR_EERICR)* are set.

Error Injection mode is configured by the EIM configuration bit in the *ECC Error Report and Injection Control Register (FR_EERICR)*. When error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

51.6.25.1 CHI LRAM error injection

The following sequence describes an memory error injection sequence for the CHI LRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke an distortion of the memory content. The content of the CHI LRAM is described in [Table 1097](#).

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see [Section 51.7.3, "Memory error injection out of POC:default config"](#).

Injector setup:

1. FR_MCR[ECCE]:= 1;
// enable ECC functionality
2. FR_EERICE[EIE]:=I_MODE;
// configure error injection mode
3. FR_EEIAR[MID]:= 1;
// select CHI LRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
// select bank for error injection; I_BANK = {0,1,2,3,4,5}
5. FR_EEIAR[ADDR]:= I_ADDR;
// select address for error injection; I_ADDR ≤ 0x56
6. FR_EEIDR[DATA]:= D_DIST;
// define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
// define checkbit distortion pattern
8. FR_EERICE[EIE]:=1;
// enable error injection

Application Write Access:

```
If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;
If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;
If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;
If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;
If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;
If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;
// write DATA to the defined injection bank and injection address (see Table 1097).
```

51.6.25.2 PE DRAM error injection

The following sequence describes a memory error injection sequence for the PE DRAM memory. This sequence consists of the error injector setup followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see [Section 51.7.3.2, "PE DRAM error injection out of POC:default config"](#).

Injector setup:

1. FR_MCR[ECCE]:= 1;
// enable ECC functionality
2. FR_EERICE[EIE]:=I_MODE;
// configure error injection mode
3. FR_EEIAR[MID]:= 0;
// select PE DRAM for error injection
4. FR_EEIAR[BANK]:= I_BANK;
// define bank for error injection; I_BANK = {0,1}
5. FR_EEIAR[ADDR]:= I_ADDR;
// define address for error injection; I_ADDR ≤ 0x7F
6. FR_EEIDR[DATA]:= D_DIST;
// define data distortion pattern
7. FR_EEICR[CODE]:= C_DIST;
// define checkbit distortion pattern
8. FR_EERICE[EIE]:=1;
// enable error injection

Application write access (for example, I_ADDR=0x70):

1. FR_PEDRAR:= 0x30E0;
// INST=0x3; ADDR=0x70
2. wait until FR_PEDRAR[DAD] == 1;
// wait for end of PE DRAM access
3. val = FR_PEDRDR[DATA]; |
// get read back PE DRAM data

Note: The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

51.6.26 StopWatch function

FlexRay supports a StopWatch function to facilitate OS synchronization to the FlexRay network. This provides a capability to capture the time difference in system clocks between the operating system timer tick and the FlexRay time base. This allows the software synchronization handler to adjust the OS clock to sync with the FR macrotick.

Figure 1101. StopWatch counter logic

As shown here, there is a 32 bit stopwatch counter that resets and starts with each cycle start. This counter runs on the system clock and increments every cycle until an OS tick event is received, after which the counter halts and the count value is transferred to a shadow register. The shadow register (*Stop Watch Count Register (FR_STPWR)*) holds the counter value till the host reads all the 32 bits, after which it automatically gets cleared.

The StopWatch logic is controlled through a control bit STPW_EN in the FR_PEOER (*Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)*). The counter runs only when this bit is set.

Figure 1102 shows the actual timing of the stopwatch counter logic operation.

Figure 1102. StopWatch function timing diagram

Note: 'Host read' implies that all 32 bits have been read out completely. Any partial read (i.e for 8/16 bits access) will not clear the StopWatch count register.

Note: "If cycle start and OS tick occurs simultaneously, timer will remain at 0. But OS_tick has a 2 stage synchronizer and cycle_start has a single stage synchronizer into chi clock domain. So simultaneously here means OS_tick_pulse and chi_cycle_start occurring at the same cycle."

51.7 Application information

51.7.1 Module configuration

This section describes essential parts of the module configuration.

51.7.1.1 Configure System Memory Access Timeout Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in the [System Memory Access Time-Out Register \(FR_SYMATOR\)](#) and the CHI clock frequency f_{CHI} in MHz fulfill [Equation 68](#)^(s).

Equation 68 $0 \leq \text{SYMATOR}[\text{TIMEOUT}] \leq \lfloor 0.45 \cdot f_{\text{CHI}} - 8 \rfloor$

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI} .

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in [Table 1103](#).

Table 1103. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
$\geq 18 \text{ MHz}$	0	$\geq 100 \text{ MHz}$	≤ 37
$\geq 23 \text{ MHz}$	≤ 2	$\geq 120 \text{ MHz}$	≤ 46
$\geq 27 \text{ MHz}$	≤ 4	$\geq 140 \text{ MHz}$	≤ 55
$\geq 32 \text{ MHz}$	≤ 6	$\geq 160 \text{ MHz}$	≤ 64
$\geq 60 \text{ MHz}$	≤ 19	$\geq 180 \text{ MHz}$	≤ 73
$\geq 80 \text{ MHz}$	≤ 28	$\geq 200 \text{ MHz}$	≤ 82

51.7.1.1.1 System bus wait state constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single-channel configurations and situations in which the sync frame table generation functionality is *not* used ($\text{FR_SFTCCSR}[\text{SDVEN}, \text{SIDEN}] = 0$), no timeout will be detected if fewer than $2 \times \text{SYMATOR}[\text{TIMEOUT}] + 1$ wait states will be seen on the system bus for each system bus access.

For dual-channel configurations, or situations in which the sync frame table generation functionality is used, no timeout will be detected if fewer than $\text{SYMATOR}[\text{TIMEOUT}] - 1$ wait states will be seen on the system bus for each system bus access.

s. See [Section 51.3, "Controller Host Interface clocking"](#) for all constraints of minimum CHI clock frequency.

51.7.1.2 Configure data field offsets

The data field offsets are located in the [Message Buffer Data Field Offset Registers \(FR_MBDORn\)](#) and [Receive FIFO Start Data Offset Register \(FR_RFSDOR\)](#). The application has to configure the data field offset values for all message buffers that are used.

When the module is enabled, the initialization value of the FR_MBDORn[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (see [Section 51.6.19.1.1, "System bus illegal address access"](#)).

51.7.2 Initialization sequence

This section describes the steps required to initialize the CC. The first subsection describes the steps required after a system reset; the second section describes the steps required after preceding shutdown of the CC.

51.7.2.1 Module initialization

This section describes the module-related initialization steps after a system reset.

1. Configure the CC.
 - a) Configure the control bits in the [Module Configuration Register \(FR_MCR\)](#).
 - b) Configure the system memory base address in the [System Memory Base Address Register \(FR_SYMBADR\)](#).
2. Enable the CC.
 - a) Write 1 to the module enable bit MEN in the [Module Configuration Register \(FR_MCR\)](#).

The CC now enters Normal mode. The application can commence with the protocol initialization described in [Section 51.7.2.2, "Protocol initialization"](#).

51.7.2.2 Protocol initialization

This section describes the protocol-related initialization steps.

1. Configure the Protocol Engine.
 - a) Issue CONFIG command via the [Protocol Operation Control Register \(FR_POCR\)](#).
 - b) Wait for *POC:config* in the [Protocol Status Register 0 \(FR_PSR0\)](#).
 - c) Configure the FR_PCR0,..., FR_PCR30 registers to set all protocol parameters.
2. Configure the message buffers and FIFOs.
 - a) Set the number of message buffers used and the message buffer segmentation in the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#).
 - b) Define the message buffer data size in the [Message Buffer Data Size Register \(FR_MBDSR\)](#).
 - c) Configure each message buffer by setting the configuration values in the [Message Buffer Configuration, Control, Status Registers \(FR_MBCCSRn\)](#), [Message Buffer Cycle Counter Filter Registers \(FR_MBCCFRn\)](#), [Message Buffer Frame ID Registers \(FR_MBFIDRn\)](#), and [Message Buffer Index Registers \(FR_MBIDXRn\)](#).
 - d) Configure the FIFOs.
 - e) Issue CONFIG_COMPLETE command via the [Protocol Operation Control Register \(FR_POCR\)](#).
 - f) Wait for *POC:ready* in the [Protocol Status Register 0 \(FR_PSR0\)](#).

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

51.7.2.3 CHI LRAM initialization

The CHI LRAM initialization is performed by the CC when it leaves Disabled mode. The initialization runs for 87 CHI clock cycles. All fields in the FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBDORn, and LEETRn registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

51.7.2.4 PE DRAM initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs and will delay the state transition from *POC:default config* into *POC:config*.

51.7.3 Memory error injection out of *POC:default config*

This section provides information for application-driven memory error injection out of *POC:default config*. The CC provides means to inject memory errors from the application without any impacts to the internal protocol operation of the CC.

51.7.3.1 CHI LRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the *LRAM ECC Error Test Registers (FR_LEETRn)*. Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in [Section 51.6.25.1, “CHI LRAM error injection”](#).

51.7.3.2 PE DRAM error injection out of *POC:default config*

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM locations to inject memory errors into the PE DRAM. The injection sequence is described in [Section 51.6.25.2, “PE DRAM error injection”](#).

51.7.4 Shutdown sequence

This section describes a secure shutdown sequence to stop the CC gracefully. The main targets of this sequence are

- Finish all ongoing reception and transmission
- Do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication

For a graceful shutdown, the application should perform the following tasks:

1. Disable all enabled message buffers.
 - a) Repeatedly write 1 to FR_MBCCSRn[EDT] until FR_MBCCSRn[EDS] == 0.
2. Stop the Protocol Engine.
 - a) Issue HALT command via [Protocol Operation Control Register \(FR_POCR\)](#).
 - b) Wait for *POC:halt* in [Protocol Status Register 0 \(FR_PSR0\)](#).

51.7.5 Number of usable message buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#), a configured mini-slot length [gdMinislot](#), and a configured nominal macrotick length [gdMacrotick](#)^(t).

Additional constraints for the minimum CHI clock frequency are given in [Section 51.3, "Controller Host Interface clocking"](#).

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of the slot and must be finished before the start of the next slot.

The shortest FlexRay slot is a corrected empty dynamic slot. A corrected empty dynamic slot is a mini-slot and consists of [gdMinislot](#) corrected macroticks with a duration of [gdMacrotick](#). The minimum duration of an corrected macrotick is [gdMacrotick](#)_{min} = 39 μT. This results in a minimum length of an correct slot

Equation 69 $\Delta_{\text{slotmin}} = 39 \cdot \text{pdMicrotick} \cdot \text{gdMinislot}$

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers [FR_MBSSUTR\[LAST_MB_UTIL\] + 1](#) and for a given CHI clock frequency f_{chi} , this results in a search duration of

Equation 70 $\Delta_{\text{search}} = \frac{1}{f_{\text{chi}}} \cdot (\text{FR_MBSSUTR[LAST_MB_UTIL]} + 27)$

The message buffer search must be finished within one slot which requires that [Equation 71](#) must be fulfilled:

Equation 71 $\Delta_{\text{search}} \leq \Delta_{\text{slotmin}}$

This results in the formula given in [Equation 72](#) which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

Equation 72 $f_{\text{chi}} \geq \frac{(\text{FR_MBSSUTR[LAST_MB_UTIL]} + 27)}{39 \cdot \text{pdMicrotick} \cdot \text{gdMinislot}}$

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the [Message Buffer Segment Size and Utilization Register \(FR_MBSSUTR\)](#) set to 127 is given in [Table 1104](#).

t. see [Section 51.3, "Controller Host Interface clocking"](#) for all constraints of minimum CHI clock frequency.

Table 1104. Minimum f_{chi} [MHz] examples (128 message buffers used)

<i>pdMicrotick</i> [ns]	gdMinislot					
	2	3	4	5	6	7
25.0	79.5	53	39.8	31.8	26.5	22.8
50.0	39.8	26.5	19.9	15.9	13.3	11.4

Note: If the minimum CHI frequency is not met the *CHIERFR[MBS_EF]* flag is set. Refer to [Section 51.5.2.17, "CHI Error Flag Register \(FR_CHIERFR\)"](#) for details.

51.7.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of [Table 984](#) by writing the command to the POCCMD field of the [Protocol Operation Control Register \(FR_POCCR\)](#). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in [Table 1105](#). If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the [Protocol Interrupt Flag Register 1 \(FR_PIFR1\)](#). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by [Table 1105](#). If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 1105. Protocol control command priorities

Protocol command	Priority	Interrupted by	Cleared and terminated by
FREEZE	(highest) 1	none	
READY	2		
CONFIG_COMPLETE	3		

Table 1105. Protocol control command priorities (continued)

Protocol command	Priority	Interrupted by	Cleared and terminated by
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLETE, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE, fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(lowest) 10		FREEZE, READY, CONFIG_COMPLETE, fatal protocol error

51.7.7 Message buffer search on simple message buffer configuration

This section describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

51.7.7.1 Simple message buffer configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot S . The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number t and has following configuration

Table 1106. Transmit buffer configuration

Register	Field	Value	Description
FR_MBCCSR t	MTD	1	Transmit buffer
FR_MBCCFR t	MTM	0	Event Transition mode
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000011	Cycle set = $\{4n\} = \{0,4,8,12,\dots\}$
	CCFVAL	000000	
FR_MBFIDR t	FID	S	Assigned to slot S

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSR t [CMT] and the lock bit FR_MBCCSR t [LCKS].

The receive message buffer has the message buffer number r and has following configuration

Table 1107. Receive buffer configuration

Register	Field	Value	Description
FR_MBCCSR r	MTD	0	Receive buffer
FR_MBCCFR r	MTM	—	n/a
	CHA	1	Assigned to channel A
	CHB	0	Not assigned to channel B
	CCFE	1	Cycle counter filter enabled
	CCFMSK	000001	Cycle set = $\{2n\} = \{0,2,4,6,\dots\}$
	CCFVAL	000000	
FR_MBFIDR r	FID	S	Subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSR t [EDS] = 1 and FR_MBCCSR r [EDS] = 1)

Note: The cycle set $\{4n+2\} = \{2,6,10,\dots\}$ is assigned to the receive buffer only.
The cycle set $\{4n\} = \{0,4,8,12,\dots\}$ is assigned to both buffers.

51.7.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot S in the *static* segment.

The configuration of a transmit buffer for a static slot S assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot S . In any case, the result of the message buffer search will be the transmit message buffer t . The receive message buffer r will not be found, no reception is possible.

51.7.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot s in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

51.7.7.3.1 Transmit Data Not Available

If transmit data are *not available*, that is, the transmit buffer is not committed FR_MBCCSR{[CMT]=0 and/or locked FR_MBCCSR{[LCKS]=1,

- For the cycles in the set $\{4n\}$, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and
- For the cycles in the set $\{4n+2\}$, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in [Figure 1103](#).

Figure 1103. Transmit data not available

51.7.7.3.2 Transmit data available

If transmit data are *available*, that is, the transmit buffer is committed FR_MBCCSRt[CMT] = 1 and not locked FR_MBCCSRt[LCKS] = 0,

- For the cycles in the set $\{4n\}$, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.
- For the cycles in the set $\{4n+2\}$, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in [Figure 1104](#).

Figure 1104. Transmit data available

52 Inter-Integrated Circuit (I²C)

52.1 Overview

This chapter describes the Inter-Integrated Circuit (I²C) bus module implemented on this chip and presents the following topics:

- [Section 52.2, Introduction to I²C](#)
- [Section 52.3, External signal descriptions](#)
- [Section 52.4, Memory map and register definition](#)
- [Section 52.5, Functional description](#)
- [Section 52.6, Initialization/application information](#)

52.2 Introduction to I²C

This section presents the following topics:

- [Section 52.2.1, Definition: I²C module](#)
- [Section 52.2.2, Advantages of the I²C bus](#)
- [Section 52.2.3, Module block diagram](#)
- [Section 52.2.4, Features](#)
- [Section 52.2.5, Modes of operation](#)
- [Section 52.2.6, Definition: I²C conditions](#)

52.2.1 Definition: I²C module

The I²C module is a functional unit that provides a two-wire — serial data (SDA) and serial clock (SCL) — bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

52.2.2 Advantages of the I²C bus

The synchronous, multiple-master two-wire I²C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously
- Does not require an external address decoder

52.2.3 Module block diagram

[Figure 1105](#) shows a block diagram of the I²C module.

Figure 1105. I²C block diagram

52.2.4 Features

The I²C module has the following key features:

- Compatible with I²C bus standard^(u)
- Operating speeds
 - Up to 100 kbps in Standard Mode
 - Up to 400 kbps in Fast Mode
 - Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
 - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Multi-master operation
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

52.2.5 Modes of operation

The I²C module supports the chip modes described in [Table 1108](#).

Table 1108. Chip modes supported by the I²C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I ² C module	The I ² C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus.
IPG DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See Section 52.5.6, IPG DEBUG mode .

In addition to chip modes, the I²C module has several module-specific modes. These are described in [Table 1109](#).

u. Compliant with I²C 2.0 standard with the exception that HS (high speed) mode is not supported

Table 1109. Module-specific modes supported by the I²C module

Module mode	Description	Important notes
Master mode	The I ² C module is the driver of the SDA line.	- Do not use the I²C module's slave address as a calling address. - The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I ² C module is not the driver of the SDA line.	- Enable the I²C module before a START condition from a non-I²C master is detected. - By default the I²C module performs as a slave receiver.

52.2.6 Definition: I²C conditions

Table 1110 shows the I²C-specific conditions defined for the I²C module.

Table 1110. I²C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in Figure 1106 .
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in Figure 1106 .
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

**Figure 1106. START and STOP conditions**

52.3 External signal descriptions

This section presents the following topics:

- [Section 52.3.1, Signal overview](#)
- [Section 52.3.2, Detailed external signal descriptions](#)

52.3.1 Signal overview

The I²C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

52.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in [Table 1111](#).

Table 1111. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I ² C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I ² C bus specification

52.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I²C module. It presents the following topics:

- [Section 52.4.1, I²C memory map](#)
- [Section 52.4.2, Register accessibility](#)
- [Section 52.4.3, Register figure conventions](#)
- [Section 52.4.4, I²C Bus Address Register \(IBAD\)](#)
- [Section 52.4.5, I²C Bus Frequency Divider Register \(IBFD\)](#)
- [Section 52.4.6, I²C Bus Control Register \(IBCR\)](#)
- [Section 52.4.7, I²C Bus Status Register \(IBSR\)](#)
- [Section 52.4.8, I²C Bus Data I/O Register \(IBDR\)](#)
- [Section 52.4.9, I²C Bus Interrupt Config Register \(IBIC\)](#)
- [Section 52.4.10, I²C Bus Debug Register \(IBDBG\)](#)

52.4.1 I²C memory map

The memory map for the I²C module is given below in [Table 1112](#). The total address for each register is the sum of the base address for the I²C module and the address offset for each register.

Table 1112. I²C memory map

Address Offset	Register	Access	Reset value	Section/Page
0x0000	IBAD—I ² C Bus Address Register	R/W	0x00	52.4.4/2071
0x0001	IBFD—I ² C Bus Frequency Divider Register	R/W	0x00	52.4.5/2071
0x0002	IBCR—I ² C Bus Control Register	R/W	0x80	52.4.6/2072
0x0003	IBSR—I ² C Bus Status Register	R/W	0x80	52.4.7/2073
0x0004	IBDR—I ² C Bus Data I/O Register	R/W	0x00	52.4.8/2075
0x0005	IBIC—I ² C Bus Interrupt Config Register	R/W	0x00	52.4.9/2076
0x0006	IBDBG—I ² C Bus Debug Register	R/W	0x00	52.4.10/2076
0x0007 – 0x3FFF	Reserved ⁽¹⁾			

1. If enabled at the SoC level, reads or writes to these registers will cause bus aborts. Refer to the System Services Module documentation for more details.

52.4.2 Register accessibility

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

52.4.3 Register figure conventions

The register figures show the field structure using the conventions in [Figure 1107](#).

Figure 1107. Register figure conventions

52.4.4 I²C Bus Address Register (IBAD)

This register contains the address the I²C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Figure 1108. I²C Bus Address register (IBAD)

Table 1113. IBAD field descriptions

Field	Description
0–6 ADR	Slave Address. Specific slave address to be used by the I ² C Bus module. <i>Note: The default mode of I²C Bus is slave mode for an address match on the bus.</i>
7	Reserved, should be cleared; will always read 0.

52.4.5 I²C Bus Frequency Divider Register (IBFD)

Figure 1109. I²C Bus Frequency Divider Register (IBFD)

Table 1114. IBFD field descriptions

Field	Description
0–7 IBC	I-Bus Clock Rate. This field is used to prescale the clock for bit rate selection. The bit clock generator is implemented as a prescale divider. The IBC bits are decoded to give the Tap and Prescale values as follows: 0–1 Selects the prescaled shift register (see Table 1123) 2–4 Selects the prescaler divider (see Table 1124) 5–7 Selects the shift register tap point (see Table 1125)

52.4.6 I²C Bus Control Register (IBCR)Figure 1110. I²C Bus Control Register (IBCR)

Offset 0x0002

Access: Supervisor

	0	1	2	3	4	5	6	7
R	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	0
W						RSTA		
Reset	1	0	0	0	0	0	0	0

Table 1115. IBCR field descriptions

Field	Description
0 MDIS	Module disable. This bit controls the software reset of the entire I²C Bus module. 0 The I²C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled. <i>Note: If the I²C Bus module is enabled in the middle of a byte transfer, the interface behaves as follows: slave mode ignores the current transfer on the bus and starts operating whenever a subsequent start condition is detected. Master mode will not be aware that the bus is busy, hence if a start cycle is initiated then the current bus cycle may become corrupt. This would ultimately result in either the current bus master or the I²C Bus module losing arbitration, after which, bus operation would return to normal.</i>
1 IBIE	I-Bus Interrupt Enable. 0 Interrupts from the I²C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I²C Bus module are enabled. An I²C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select. When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. This field is cleared without generating a STOP signal when the master loses arbitration. 0 Slave Mode 1 Master Mode
3 TXRX	Transmit/Receive mode select. This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit

Table 1115. IBCR field descriptions (continued)

Field	Description
4 NOACK	Data Acknowledge disable. This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I ² C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. <i>Note: Values written to this bit are only used when the I²C Bus is a receiver, not a transmitter.</i> 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data 1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)
5 RSTA	Repeat Start. Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. Attempting a repeated start at the wrong time, if the bus is owned by another master, will result in loss of arbitration. 0 No effect 1 Generate repeat start cycle
6 DMAEN	DMA Enable. When this bit is set, the DMA Tx and Rx lines will be asserted when the I ² C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if the loss of arbitration or addressed as slave conditions occur. The DMA mode is only valid when the I ² C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals

52.4.7 I²C Bus Status Register (IBSR)

Figure 1111. I²C Bus Status Register (IBSR)

Offset 0x0003

Access: Supervisor⁽¹⁾

	0	1	2	3	4	5	6	7
R	TCF	IAAS	IBB	IBAL	0	SRW	IBIF	RXAK
W				w1c			w1c	
Reset	1	0	0	0	0	0	0	0

1. With the exception of IBIF and IBAL are w1c.

Table 1116. IBSR field descriptions

Field	Description
0 TCF	Transfer complete. While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. <i>Note: This bit is only valid during or immediately following a transfer to the I²C module or from the I²C module.</i> 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave. When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy. This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. 0 Bus is Idle 1 Bus is busy
3 IBAL	Arbitration Lost. The arbitration lost bit (IBAL) is set by hardware when the arbitration procedure is lost. Arbitration is lost in the following circumstances: – SDA is sampled low when the master drives a high during an address or data transmit cycle. – SDA is sampled low when the master drives a high during the acknowledge bit of a data receive cycle. – A start cycle is attempted when the bus is busy. – A repeated start cycle is requested in slave mode. – A stop condition is detected when the master did not request it. This bit must be cleared by software, by writing a one to it. A write of zero has no effect.
4 Reserved	Reserved
5 SRW	Slave Read/Write. When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By programming this bit, the CPU can select slave transmit/receive mode according to the command of the master. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave

Table 1116. IBSR field descriptions (continued)

Field	Description
6 IBIF	I-Bus Interrupt Flag. The IBIF bit is set when one of the following conditions occurs: – Arbitration lost (IBAL bit set) – Byte transfer complete (TCF bit set and DMAEN bit not set) – Addressed as slave (IAAS bit set) – NoAck from Slave (MS & Tx bits set) – I²C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge. This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

52.4.8 I²C Bus Data I/O Register (IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

Note: The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I²C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I²C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I²C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/W bit (in position D0).

Table 1119. IBDBG field descriptions

Field	Description
6 IPG_DEBUG_HALTED	Debug Halted Bit: This is a status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode
7 IPG_DEBUG_EN	Debug enable bit. This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. 0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode <i>Note: If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited.</i>

52.5 Functional description

This section presents the following topics:

- [Section 52.5.1, Notes about module operation](#)
- [Section 52.5.2, Transactions](#)
- [Section 52.5.3, Arbitration procedure](#)
- [Section 52.5.4, Clock behavior](#)
- [Section 52.5.5, Interrupts](#)
- [Section 52.5.6, IPG DEBUG mode](#)
- [Section 52.5.7, DMA interface](#)

52.5.1 Notes about module operation

- The I²C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I²C module is acting as a master, it must not try to call its own slave address.

52.5.2 Transactions

This section presents the following topics:

- [Section 52.5.2.1, Protocol overview](#)
- [Section 52.5.2.2, Transaction protocol definitions](#)
- [Section 52.5.2.4, High-level protocol steps](#)
- [Section 52.5.2.5, START condition](#)
- [Section 52.5.2.6, Slave address transmission](#)
- [Section 52.5.2.7, Data transmission](#)
- [Section 52.5.2.8, STOP condition](#)
- [Section 52.5.2.9, Repeated START condition](#)

52.5.2.1 Protocol overview

Figure 1115 shows the behavior of SCL and SDA during a typical I²C transaction.

Figure 1115. I²C transaction protocol

52.5.2.2 Transaction protocol definitions

This section defines several important terms presented in Figure 1115.

Table 1120. I²C definitions

Term	Definition
START	A START condition, as defined in Section 52.2.6, Definition: I2C conditions
STOP	A STOP condition, as defined in Section 52.2.6, Definition: I2C conditions
Calling (slave) address	A seven-bit address used to identify a slave on the I ² C bus. The requirements for specifying this address are presented in Section 52.5.2.3, I2C calling address requirements .
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: – 0 = The data is being transferred from the master to the slave ("write") – 1 = The data is being transferred from the slave to the master ("read")
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

52.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

52.5.2.4 High-level protocol steps

The I²C protocol conceptually supports two types of transfers, which are illustrated in [Figure 1115](#). The significant steps in these transfers are presented in [Table 1121](#). Details of each of these steps are presented in subsequent sections.

Table 1121. I²C high-level protocol steps

Standard Transfer	Repeated START Transfer
1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. STOP condition 6. (repeat Steps 1–4)	1. START condition 2. Slave target or general call address transmission 3. Acknowledgment from slave 4. Data transfer 5. Repeated START condition 6. (repeat Steps 2–4 as needed) 7. STOP condition. 8. (repeat Steps 1–7)

52.5.2.5 START condition

When the bus is free, that is, no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (see [Section 52.2.6, Definition: I²C conditions](#)). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

52.5.2.6 Slave address transmission

The master transmits the slave address immediately after the START condition (see [Section 52.5.2.5, START condition](#)). The process of slave address transmission is presented in [Table 1122](#).

Table 1122. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: – The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. – The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

52.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the $\overline{R/W}$ bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

52.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see [Section 52.2.6, Definition: I2C conditions](#)). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see [Section 52.5.2.9, Repeated START condition](#).

52.5.2.9 Repeated START condition

The I²C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of [Figure 1115](#).

52.5.3 Arbitration procedure

The I²C bus is a true multi-master bus that allows more than one master to be connected to it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic "1" while another master transmits logic "0". The losing masters immediately switch over to slave receive mode and stop driving the SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

52.5.4 Clock behavior

This section presents the following topics:

- [Section 52.5.4.1, Clock synchronization](#)
- [Section 52.5.4.2, Clock stretching](#)
- [Section 52.5.4.3, Handshaking](#)
- [Section 52.5.4.4, Clock rate and IBFD settings](#)

52.5.4.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached. However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see [Figure 1116](#)). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

Figure 1116. I²C bus clock synchronization

52.5.4.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

52.5.4.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it

halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

52.5.4.4 Clock rate and IBFD settings

The following tables describe the settings of several fields in the IBFD register (see [Section 52.4.5, I2C Bus Frequency Divider Register \(IBFD\)](#)).

Table 1123. I-Bus multiplier factor

IBC	MUL
00	01
01	02
10	04
11	Reserved

Table 1124. I-Bus prescaler divider values

IBC	scl2start (clocks)	scl2stop (clocks)	scl2tap (clocks)	tap2tap (clocks)
000	2	7	4	1
001	2	7	4	2
010	2	9	6	4
011	6	9	6	8
100	14	17	14	16
101	30	33	30	32
110	62	65	62	64
111	126	129	126	128

Table 1125. I-Bus tap and prescale values

IBC	SCL Tap (clocks)	SDA Tap (clocks)
000	5	1
001	6	1
010	7	2
011	8	2
100	9	3
101	10	3
110	12	4
111	15	4

The number of clocks from the falling edge of SCL to the first tap (Tap[1]) is defined by the values shown in the scl2tap column of [Table 1124](#). All subsequent tap points are separated by 2^{IBC} as shown in the tap2tap column in [Table 1124](#). The SCL Tap is used to generate the SCL period and the SDA Tap is used to determine the delay from the falling edge of SCL to the change of state of SDA that is the SDA Hold time.

Figure 1117. SDA Hold time

Figure 1118. SCL Divider and SDA Hold

The equation used to generate the divider values from the IBFD bits is:

$$\text{Equation 73} \quad \text{SCL Divider} = \text{MUL} \times \{2 \times (\text{scl2tap} + [(\text{SCL_Tap} - 1) \times \text{tap2tap}] + 2)\}$$

The SDA Hold delay is equal to the CPU clock period multiplied by the SDA Hold value shown in [Table 1126](#). The equation used to generate the SDA Hold value from the IBFD bits is:

$$\text{Equation 74} \quad \text{SDA Hold} = \text{MUL} \times \{\text{scl2tap} + [(\text{SDA_Tap} - 1) \times \text{tap2tap}] + 3\}$$

The equations for SCL Hold values to generate the START and STOP conditions from the IBFD bits are:

Equation 75 $\text{SCL Hold(start)} = \text{MUL} \times [\text{scl2start} + (\text{SCL_Tap} - 1) \times \text{tap2tap}]$

Equation 76 $\text{SCL Hold(stop)} = \text{MUL} \times [\text{scl2stop} + (\text{SCL_Tap} - 1) \times \text{tap2tap}]$

52.5.5 Interrupts

This section presents the following topics:

- [Section 52.5.5.1, Interrupt vector](#)
- [Section 52.5.5.2, Interrupt description](#)

52.5.5.1 Interrupt vector

The I²C module uses only one interrupt vector.

Table 1127. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I ² C Interrupt	—	—	—	IBAL, TCF, IAAS, IBB bits in IBSR register	When any of IBAL, TCF or IAAS bits is set, an interrupt may be caused based on Arbitration lost, Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

52.5.5.2 Interrupt description

There are five types of internal interrupts in the I²C. The interrupt service routine can determine the interrupt type by reading the Status register.

I²C Interrupt can be generated on the following events:

- Arbitration Lost condition (IBAL bit set)
- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)
- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I²C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIIE] bit.

52.5.6 IPG DEBUG mode

This mode allows CPU to debug the I²C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I²C comes to a graceful halt after completing all the ongoing transactions. A Debug halted signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I²C module enters IPG DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I²C module enters this mode only after successfully completing the current ongoing transaction. No more transaction can take place until the debug signal is de-asserted after which the I²C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I²C module has entered the IPG DEBUG mode. See [Figure 1119](#) for more details.

Figure 1119. IPG DEBUG mode

[Figure 1120](#) shows a case of IPG DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I²C module enters IPG DEBUG mode.

Figure 1120. IPG debug mode with repeated start

52.5.7 DMA interface

A simple DMA interface is implemented so that the I²C can request data transfers with minimal support from the CPU. DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I²C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I²C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the [Section 52.6, Initialization/application information](#), of this document.

52.6 Initialization/application information

This section presents the following topics:

- [Section 52.6.1, Recommended interrupt service flow](#)
- [Section 52.6.2, General programming guidelines \(for both master and slave mode\)](#)
- [Section 52.6.3, Programming guidelines specific to master mode](#)
- [Section 52.6.4, Programming guidelines specific to slave mode](#)
- [Section 52.6.5, DMA application information](#)

52.6.1 Recommended interrupt service flow

[Figure 1121](#) shows a flowchart for the recommended I²C interrupt service routine. Deviation from the flowchart may result in unpredictable I²C bus behavior.

Figure 1121. Recommended I²C interrupt service routine flowchart

52.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I²C module in both master and slave mode. It presents the following topics:

- [Section 52.6.2.1, Initializing the I²C module](#)
- [Section 52.6.2.2, Software response after a transfer](#)

52.6.2.1 Initializing the I²C module

The following sequence initializes the I²C module:

1. Use the IBFD register to select the required division ratio to obtain SCL frequency from system clock.
2. Use the IBAD register to define the slave address.
3. Clear the IBCR[IBDIS] bit to enable the I²C interface system.
4. Use the IBCR to select Master/Slave mode, Transmit/Receive mode and interrupt enable or not.
5. (Optional) Use the IBIC register to further refine the interrupt behavior.

52.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I²C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I²C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I²C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled. Polling should monitor the IBIF bit rather than the TCF bit since their operation is different when arbitration is lost.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

52.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- [Section 52.6.3.1, Generating START](#)
- [Section 52.6.3.2, Transmit/receive sequence](#)
- [Section 52.6.3.3, Generating STOP](#)
- [Section 52.6.3.4, Generating repeated START](#)
- [Section 52.6.3.5, Loss of arbitration](#)

52.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I²C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I²C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1) // wait in loop for IBB flag to clear
  IBCR[MS/MSL] and IBVR[ ]Tx/Rx] = 1 //master and transmit mode, that is,
  generate start condition
  IBDR = calling_address // send the calling address to the data register
  while (bit 5, IBSR ==0) // wait in loop for IBB flag to be set
```

52.6.3.2 Transmit/receive sequence

Below sequence to be followed in case of Master Transmit (Address/Data):

- Clear IBIF in IBSR register.
- Write data in Data Register (IBDR).
- TCF bit will get cleared in IBSR register when transfer is in progress.
- TCF bit will get set in IBSR register when transfer is complete.
- Wait for IBIF to get set in IBSR register, then read IBSR register to determine its source
 - TCF = 1 that is transfer is complete.
 - No Acknowledge condition (RXAK = 1) is found.
 - IBB = 0 that is Bus has transitioned from Busy to Idle state.
 - If IBB = 1, ignore check of Arbitration Loss (IBAL = 1).
 - Ignore Address Detect (IAAS = 1) for Master mode (valid only for Slave mode).
- Check RXAK in IBSR for an acknowledge from slave.

Below sequence to be followed in case of Slave Receive (Address/Data):

- a) Clear IBIF in IBSR register.
- b) TCF bit will get cleared in IBSR register when transfer is in progress for address transfer.
- c) TCF bit will get set in IBSR register when transfer is complete.
- d) Wait for IBIF to get set in IBSR register. Then read IBSR register to determine its source:
 - Address Detect has occurred (IAAS = 1) — determination of Slave mode.
- e) Clear IBIF.
- f) Wait till TCF bit gets cleared in IBSR register (that is “Transfer under Progress” condition is reached for data transfer).
- g) Wait till TCF bit gets cleared in IBSR register (proof that Transfer Completes from “Transfer under Progress” state).
- h) Wait till IBIF bit gets set in IBSR register. To find its source, check if:
 - TCF = 1 that is reception is complete.
 - IBB= 0 in IBSR register i.e. Bus has transitioned from Busy to Idle state.
 - Ignore Arbitration Loss (IBAL = 1) for IBB = 1.
 - Ignore No Acknowledge condition (RXAK = 1) for receiver.
- i) Read the Data Register (IBDR) to determine data received from Master.

Sequence followed in case of Slave Transmit (Steps a-d of Slave Receive for Address Detect, followed by a-f of Master Transmit for Data Transmit).

Sequence followed in case of Master Receive (Steps a-f of Master Transmit for Address dispatch, followed by e-h of Slave Receive for Data Receive)

52.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```

if (tx_count == 0) or// check to see if all data bytes have been
transmitted
    (bit 0, IBSR == 1) {// or if no ACK generated
        clear bit 5, IBCR// generate stop condition
    }
else {
    IBDR = data_to_transmit// write byte of data to DATA register
    tx_count --// decrement counter
} // return from interrupt

```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```

rx_count --// decrease the rx counter
if (rx_count ==1)// 2nd last byte to be read ?

```

```
    bit 3, IBCR = 1// disable ACK
if (rx_count == 0)// last byte to be read ?
    bit 5, IBCR = 0// generate stop signal
else
    data_received = IBDR// read RX data and store
```

52.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```
    bit 2, IBCR = 1// generate another start (restart)
    IBDR == calling_address// transmit the calling address
```

52.6.3.5 Loss of arbitration

If several masters try to engage the bus simultaneously, only one master wins and the others lose arbitration. The devices that lost arbitration are immediately switched to slave receive mode by the hardware. Their data output to the SDA line is stopped, but SCL is still generated until the end of the byte during which arbitration was lost. An interrupt occurs at the falling edge of the ninth clock of this transfer with IBAL=1 and MS/SL=0. If one master attempts to start transmission, while the bus is being engaged by another master, the hardware will inhibit the transmission, switch the MS/SL bit from 1 to 0 without generating a STOP condition, generate an interrupt to CPU and set the IBAL to indicate that the attempt to engage the bus is failed. When considering these cases, the slave service routine should test the IBAL first and the software should clear the IBAL bit if it is set.

52.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an “end of data” signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

52.6.5 DMA application information

The DMA interface on the I²C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMA enable bit in the control register is not set when the I²C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I²C block.

The CPU should also keep the I²C interrupt enabled during a DMA transfer to detect the arbitration lost condition and take action to recover from this situation. The DMAEN bit in the IBCR register works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, dependant on the setting of the DMAEN bit. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I²C should never be configured for slave operation.

The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place. The sections present the following topics:

- [Section 52.6.5.1, DMA mode, master transmit](#)
- [Section 52.6.5.2, DMA mode, master reception](#)
- [Section 52.6.5.3, Exiting DMA mode, system requirement considerations](#)

52.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit “n” data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

Figure 1122. Flow-Chart of DMA mode master transmit

52.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive “n” data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

Figure 1123. Flow-Chart of DMA mode master receive

52.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I²C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is

that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I²C module.

After the last DMA write (TX mode) to the I²C the module will immediately start the next I²C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I²C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

The DMAEN bit is cleared before the next I²C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

The DMAEN bit is cleared after the next I²C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I²C is the time required for one byte transfer over the I²C. For 'fast reaction' the disabling has to occur before the 9th bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

Equation 77 $T_R = 8 \times T_{SCL}$

In fast mode, with 400 kbit/s, T_{SCL} is 2.5 μ s, so T_R is 20 μ s.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act accordingly. In case of slow reaction you can force an interrupt for the I²C in the interrupt controller to have the further transfer handled by the normal I²C interrupt routine.

Note: The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking (if supported)

The Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to the I²C IBCR register to disable the DMAEN bit. This is probably the fastest system solution, but it uses two DMA channels.

Note: Here you have to make sure on system level that no higher priority DMA requests occur between the two linked TCDs as those could again create a scenario of slow reaction.

3. DMA scatter/gather process (if supported)

The Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated. This feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the I²C IBCR register to disable the DMAEN bit. This TCD also has scatter/gather activated and is programmed

to reload the initial TCD upon completion, bringing the system back into a “ready-for-I²C-transfer” state. The advantage over the two other solutions is that this neither requires CPU intervention nor a 2nd DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note: Here you have to make sure at system level that no higher priority DMA requests occur during the scatter/gather process, as those could again create a scenario of slow reaction.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I²C connected via half speed IPI bus:

- Accessing the I²C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I²C could be faster):

Equation 78 $4 \times T_{IPI} = 4 / 16 \text{ MHz} = 250 \text{ ns}$

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

Equation 79 $8 \times T_{AHB} = 8 / 32 \text{ MHz} = 250 \text{ ns}$

With the DMA scatter/gather process the required IBCR access can be done in 0.5 μs, leaving a large margin of 19.5 μs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

53 Peripheral Sensor Interface (PSI5)

53.1 Introduction

The PSI5 interface offers power supply and data transfer between the application and multiple sensors over a two-wire interface. Data transmission from the application to the sensor or sensors is achieved through modulation of the power supply voltage (sync pulse). Data reception from the sensor or sensors to the application is achieved through modulation of the current drawn by a sensor using Manchester encoding.

At the system level, the PSI5 interface consists of mechanisms integrated on the microcontroller and an external physical layer that provides the high-voltage supply and converts the current drawn by the sensor into a digital Manchester-encoded data stream.

53.1.1 Overview

The PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make the PSI5 also suitable for many other automotive sensor applications. The development goal of the PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented free of charge.

The main features of the PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 Kbit/s or optional 189 Kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication
- In short, PSI5 standardizes the low-level communication between peripheral sensors and electronic control units. Note that the physical layer for the IP (transceiver) is to be implemented separately outside the IP.

Figure 1124. PSI5 digital interface block diagram

Format1: Stored in RAM Registers

O	F	E	M	E	T	Slot Counter	Time Stamp	Header+ Sensor Data(i)	CRC or Parity bits	C
---	---	---	---	---	---	--------------	------------	------------------------	--------------------	---

1. "C" is set to 1 when CRC or Parity check identifies Error.
2. "T" is set to 1 at timing errors of the incoming frame.
3. "E&EM" is set to 1 at electric errors at any bit PSI5/SMC
4. "F" is set to 1 if no frame received in the slot.
5. "O" is set to 1 if any new frame overwrites prev Unread.Fr.
6. "Slot Counter" Gives the slot number in which the start bits of the frame were detected.
7. "Sensor Data" are stored in RAM automatically after all data bits are received in data receive register.
8. "Time Stamp" is appended to received frame in once start bits are received or rise edge of sync pulse.

53.1.2 Features

- IPS interface for register read/write (big endian)
- Supports bidirectional full duplex operations, but with differing baud rate—low, ECU-to-sensor, fast sensor to ECU
- Manchester decoder operating at both 125 Kbit/s and 189 Kbit/s bit rates with $\times 32$ sample clock rate
- One 64-bit sensor data receive register to which the decoded received sensor data—including header, data, timestamp, frame counter, status bits (E, EM, T, C, F) and CRC, but not including start bits—are written
- A 24-bit time stamp register with a 1 μ s (or the GTM clock) resolution. When first rising edge of start bits (S0) of a message or the rising edge of the SYNC pulse is recognized, the value in the time stamp register will be written to the data receive register
- Provision of resetting the Time Stamp Counter through the reset from the GTM module
- Single 32×64 -bit RAM buffer for storing (moving) content of the data receive register once end of message is recognized
 - Related to each RAM buffer are two diagnostic registers, N and EI. Register N is used to identify the occurrence of new messages in the corresponding RAM buffer, while register EI identifies the error status of these messages. The errors that can set the EI register bits are the F (no frame), E (electrical error), EM (electrical error for SMC bits embedded in PSI5 messages), T (Timing bit error)

and C (CRC error). Which of these errors actually set the EI register bits is configurable.

- DMA support for transferring RAM data (including diagnostic data) to system memory
- DMA transfer through IPS bus
- Support for optional serial messaging channel (SMC) and additional logic to extract SMC frames from PSI5 frames
- Operating modes supported:
 - Asynchronous mode (sensor periodically sends data, no sync pulse, one sensor per interface)
 - Synchronous mode (sync pulse generated, multiple sensor per interface)
- Sync pulse generation for synchronous modes
 - The start of each time slot (1 to 6) (see [Figure 1171](#)) on the bus (after the end of the sync pulse) can be defined with a 1 μ s resolution
 - The end of the last time slot on the bus can be defined with a 1 μ s resolution, up to a maximum sync period time of 16 ms
 - Trigger logic to generate sync pulses
 - 16-bit Channel Trigger Counter (CTC) used to generate the sync pulses by comparing the values with CIPR and CTPR
 - Counter Initialize Pulse Register (CIPR) to allow configuration of initialization (offset) period
 - Channel Trigger Period (CTP) register to allow configuration of sync period. Value in CTP is the value to which the CTC is updated after each sync pulse generation
 - Possibility to have a common 1 MHz clock source
- An upstream register bit chain consisting of Preparation Register, Buffer Register, Shift register (output data) and pulse width modulation logic, is implemented. Using this, it is possible to send a data word to the sensors through use of data sync pulses: logic 1 with programmable data sync pulse width W1, logic 0 with programmable data sync pulse width W0. The data sync pulse timing can be configured to be dependent on the periodic or event driven timing SYNC pulse. Further, there is no difference between timing sync pulse and data sync pulse during transmission (ECU-to-sensor communication).

53.1.3 Modes of operation

53.1.3.1 Disable mode

Disable mode in the PSI5 reduces power consumption. This mode is entered by setting GCR[GLOBAL_DISABLE_REQ]. All the channels enter Disable mode at once when this bit is set, irrespective of the setting of PCCR[PSI5_CH_EN] and PCCR[PSI5_CH_CONFIG]. In this mode the RX, TX and common time base counters are disabled for any operation. This is the default state after module reset is released. PSI5 can exit Disable mode by clearing the GLOBAL_DISABLE_REQ bit and enabling individual PSI5 channels (setting PCCR[PSI5_CH_EN]). Note that when entering Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter AND the internal sync pulse generator are, however, reset when entering Disable mode.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter “Configuration/Normal mode” based on the value of PCCR[PSI5_CH_CONFIG].

53.1.3.2 Initialization/Configuration mode

This is the configuration phase, in which all PSI5 global, channel specific configuration/control registers can be written. The receiver and transmitter sub-blocks are disabled in this mode. The message receive registers/buffers can be accessed in this mode. This mode can be entered by clearing GCR[GLOBAL_DISABLE_REQ] and setting PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN]. All the channel specific control registers can be programmed only in the CONFIG mode. This prevents the software from accidentally causing a change in any critical register.

53.1.3.3 Normal mode (NORMAL mode)

In Normal mode, the receiver and the transmitter blocks become active, error handling is enabled and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. Data Preparation Register, Shift Register and data output registers are writable in this mode. Apart from them, there are some register bits that can be written in this mode also. Please refer to the detailed register description. This mode can be entered clearing GCR[GLOBAL_DISABLE_REQ], clearing PCCR[PSI5_CH_CONFIG], and setting PCCR[PSI5_CH_EN].

53.1.3.3.1 PSI5 topology

The different PSI5 user operation modes define topology and parameters of the communication between ECU and sensors such as communication mode, number of data bits, error detection, cycle time, number of time slots per cycle, and bit rate.

These modes are generally denoted as

PSI5-(A / P / U / D)-dd-(P / CRC)-tttt / n(L / H)

[Table 1128](#) provides a key for these notations.

Table 1128. Normal operating states

Communication modes		Description
A	Asynchronous mode	PSI5-A describes a point-to-point connection for unidirectional, asynchronous data transmission. Each sensor is connected to the ECU by two wires. After switching on the power supply, the sensor starts transmitting data to the ECU periodically. Timing and repetition rate of the data transmission are controlled by the sensor. No Sync pulse is sent from ECU side.
P	Synchronous Parallel Bus mode	The synchronous operation modes work according to the TDMA method (Time Division Multiple Access). Each sensor is connected to the ECU by two wires. The sensor data transmission is synchronized by the ECU using voltage modulation. Synchronization (sync pulses) can be optionally used for point-to-point configurations; it is mandatory for bus modes. The sensors can be arranged as parallel bus, universal bus and daisy chain topology based on sensor addressing and interchangeability of sensors.
U	Synchronous Universal Bus mode	
D	Synchronous Daisy Chain Bus mode	

Table 1128. Normal operating states

Communication modes		Description
Data Bits		
dd	No. of data bits	
Error Detection		
P	1 parity bit	
CRC	3-bit Cyclic Redundancy Check (CRC)	
Cycle Time		
tttt	Cycle Time in μs	
n	Number of time slots per cycle	
Bit Rate		
L	125 Kbit/s	
H	189 Kbit/s	

53.1.3.4 Stop mode

When the Stop mode request is asserted, and if there is no active PSI5 transaction ongoing, then the acknowledgement to stop the clocks is given immediately. If start bits of any PSI5 packet have been detected (successful detection of both S0 and S1) then the concerned PSI5 packet is successfully stored and then the Stop mode acknowledgement is generated by the IP. Note that for generating the acknowledgement, the IP does not wait for the complete reception of any ongoing SMC message, but only waits for the complete reception of any ongoing PSI5 packet transaction.

53.1.3.5 Debug mode

In order to enter this mode the debugger has to be connected and it has to encounter a breakpoint. In addition, the `DEBUG_EN` bit has to be written to 1. The `DEBUG_EN` bit can be written by either the CPU or by the debugger but only in Configuration mode. Once the above conditions are satisfied the IP enters the Debug Mode. There are two debugging modes available. For simplicity these are being referred to as the “Freeze” and “Open” modes. The IP enters one of the above debugging modes, based on the configuration of a register bit `DEBUG_FREEZE_CTRL` mentioned in the [Section 53.3.2.2, PSI5 Channel Control Register \(PSI5_PCCR\)](#).

In “Open” mode, the core of the IP keeps on working normally and all the registers are updated from the hardware; just like they were being done in the functional mode (when the IP was out of the debug mode). Thus, even a long term entry to the Debug Mode, won't affect the normal operation of the various registers that are to be updated by the hardware. Down side is that the IP can keep on changing the internal status bits and the registers as the time progresses.

In “Freeze” mode, the core of the IP, the output and the input paths are all stopped coherently. Once the input and the output paths are stopped coherently, then all the internal status bits and registers maintain their status and value irrespective of the time progression. Coherent halting of the input path would mean that there is no active reception ongoing in

the Manchester decoder. Thus, if the Manchester decoder has already detected valid start bits(S0 and S1) and then there is a request to enter the “Freeze” mode, then the current reception is completed before the IP enters the Freeze mode. Coherent halting of the output path would mean that the “sdout” output pin of the IP should be at a logic 0. Once the above conditions are satisfied, only then can the IP enter the “Freeze” mode. Once the IP enters the Freeze mode, the time stamp counter is also halted.

In both the above modes, the various interface registers would be completely visible to the debugger, but debugger action would have no impact on the various status bits and counters that normally get affected by a CPU/DMA read. In this mode, the read pointers of the FIFO do not get incremented, when being read through the Pop-up registers. Thus in Debug mode, reading the DMA PSI5 Message Register (PSI5_DPMR), DMA SMC Frame Register (PSI5_DSFR) or the DMA Diagnostic Status Register (PSI5_DDSR) would keep on returning the same data. Hence the interrupts related to DMA completion operation would not get generated. Further the hardware clearing related to FAST_CLR_SMC and FAST_CLR_PSI5 bits would not have any effect and the hardware clearing would remain disabled. This is also highlighted in [Figure 1125](#).

Figure 1125. Block Diagram of Debug Mode

The debugger can write to all the registers just like the CPU can. However, no special privilege is given to the debugger as compared to the CPU. The read/write behavior of the debugger for various registers in Normal/Configuration mode is identical to the behavior of the CPU. Note that the various status bit and counter protections become active ONLY in Debug mode.

53.1.3.6 Operating modes

Figure shows the operating modes and Table 1129 shows the state transition.

Figure 1126. Operating modes

Note Not possible to reconfigure the PSI5 on the fly. A direct transition from the Normal to Config mode is not there to consider safety aspects.

Table 1129. State transition table

GCR [GLOBAL_DISABLE_REQ]	PCCR		State	
	[PSI5_CH_CONFIG]	[PSI5_CH_EN]	Present	Next
1	x	x	x	All channel Disable
0	x	0	x	Specific channel Disable
0	1	1	Disable	Config
0	0	1	Config	Normal

Table 1129. State transition table

GCR [GLOBAL_DISABLE_REQ]	PCCR		State	
	[PSI5_CH_CONFIG]	[PSI5_CH_EN]	Present	Next
0	x	1	Normal	Normal
0	0	1	Disable	Normal

53.2 External signal description

Table 1130. PSI5 port list

Name	Function	I/O
Signals to/from pads		
SDINn_PSI5_m ⁽¹⁾	Digital sensor data input pin of PSI5 module	I

–0x0548- 0xFFFF	Reserved						

1. In this column, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = “write-to-1-shot, always read as 0”, D = Disable mode, C = Config mode, N = Normal mode. All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable. All 16-bit registers are half word/byte addressable for write. Read is always word addressable. Trying to access any register space of PSI5, other than those mentioned in the memory map, results in the generation of transfer error. Note that the generation of transfer error is confined to this scenario only.
2. In this column, the format of the reset value indicates the register width. Thus, reset values of the formats 0xHH, 0xHHHH, and 0xHHHH_HHHH, where “H” is a hexadecimal digit, indicate 8-bit, 16-bit, and 32-bit registers, respectively.
3. No-Saf = Not Safety Relevant, Saf-Relv = Safety Relevant.
4. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0 then the reset value is “0x0000” (PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1 then the reset value is “0x0001” (PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST please refer to the Device Configuration File.
5. Not all the register bits are writable in this mode. Please see the details of the register in the Register Description section.
6. The bits can be cleared by hardware or by software using w1c. This is controlled by the “fast_clr_xxx” bit in the PSI5_PCCR. However not all bits of this register have this behavior. For details please see the register description section.
7. Writable ONLY in Config mode for test purposes. Otherwise updated by hardware.
8. The bits are set by hardware. Alternatively the software can also set these bits by writing to the corresponding SET registers. This provision should be used only for test purpose. Clearing of these bits is either by w1c or by hardware depending on the setting of the “fast_clr_xxx” bit in the PSI5_PCCR.
9. Few bits are writable to One Shot. For details please see the register details in the Register Description Section.
10. The bits of this register are writable ONLY when the corresponding DxR_RDY bit in the PSI5_GISR is equal to 1.

53.3.2 Register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode.

Note that, an access (read/write) to any register in the unimplemented register space will result in the generation of transfer error. All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to do a word operation on 16-bit registers will NOT result in the generation of any transfer error. Trying to write to “read only” bits of implemented register space, will be ignored without the generation of any error. Trying to write to any register outside its intended mode of write (Normal/config) will be ignored without the generation of any transfer error.

For a summary of the register bit accesses in various device modes, please see [Section 53.3.2.42, Device modes and Register bit accesses](#)

53.3.2.1 Global Control Register (PSI5_GCR)

The Global Control Register (PSI5_GCR) provides control functions for all the PSI5 channels simultaneously.

Figure 1127. Global Control Register (PSI5_GCR)

Address: 0000H Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	CTC_GED	GLOBAL_DISABLE_REQ
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	(1)

1. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0, then the reset value is “0” (PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1 then the reset value is “1” (PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST please refer to the Device Configuration Chapter.

Table 1132. PSI5_GCR field descriptions

Field	Description
14 CTC_GED	Channel Target Counter (CTC) Global Enable/Disable. 0 All the CTC counters having PCCR[CTC_GED_SEL] = 1 are reset. 1 Simultaneously starts the CTC of all the channels that have PCCR[CTC_GED_SEL] = 1. <i>Note: This bit is writable in all modes.</i>
15 GLOBAL_DISABLE_REQ	PSI5 Receive Global disable request. When set, all PSI5 channels enter Disable mode (from individual Normal or Config modes) regardless of the settings of the PCCR[PSI5_CH_CONFIG] and PCCR[PSI5_CH_EN] bits. When cleared, each PSI5 channel enters Config mode or Normal mode based on the setting of the PCCR[PSI5_CH_CONFIG] bit if PCCR[PSI5_CH_CONFIG] is set for that channel; otherwise, that particular channel continues to stay in Disable mode. The reset value is dependent on the parameter PSI5_PDIS_RST. When PSI5_PDIS_RST = 0 then the reset value is “0” (PSI5 module is enabled after reset). When PSI5_PDIS_RST = 1 then the reset value is “1” (PSI5 module is disabled after reset). For the value of parameter PSI5_PDIS_RST please refer to the Device Configuration Chapter. This bit is writable in all the modes. 0 PSI5 channel(s) enters Normal or Config mode, depending on the value of the PCCR[PSI5_CH_CONFIG] bit. 1 All PSI5 Channels are in Disable mode. <i>Note: When GLOBAL_DISABLE_REQ == 1 then all the clock enables (shown in Figure 1192) from the IP go to a 0 (inactive) state.</i>

53.3.2.2 PSI5 Channel Control Register (PSI5_PCCR)

Figure 1128 shows the PSI5 Channel Control Register.

Figure 1128. PSI5 Channel Control Register (PSI5_PCCR)

Table 1133. PSI5_PCCR field descriptions

Field	Description
0 CTC_GED_SEL	Channel Target Counter, Global Enable/Disable Select. This bit selects whether the CTC should be enabled/disabled by CTC_GED bit (in GCR) or the CTC_ED bit. Enabling by the CTC_GED bit is used when staggering of the channels is required. 0 CTC enabled/disabled by CTC_ED. 1 CTC enabled/disabled by CTC_GED.
1 CTC_ED	Channel Target Counter Enable/Disable. This bit is used to control the CTC locally from the channel in case the CTC_GED_SEL = 0. 0The CTC counters is disabled and reset. 1The CTC counter is enabled and start counting. <i>Note: This bit is writable in Normal mode and the Config mode.</i>
3–7 MEM_DEPTH	Can be programmed from 0 to 31 and denotes the size of the memory that should be used for storing the PSI5 messages. Area above the MEM_DEPTH is treated as being unavailable for message storage. MEM_DEPTH also denotes the number of RAM registers available for the CPU access. Note that the same memory can be accessed sequentially (though the DMA) or randomly anytime by the CPU. 0Indicates that only 1 location of the memory is available for storage 31Indicates that all the 32 locations of the memory are available for storage. <i>Note:</i> – Depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR, the MEM_DEPTH memory size may be accessed by CPU only (interrupts are generated) or CPU and DMA (through the dedicated DMA popup registers). – DMA_PM_DS_CONFIG = conf1 then DMA requests are disabled and only the interrupts can be used for data transfer. – DMA_PM_DS_CONFIG = conf2,conf3,conf4 then DMA requests are enabled. The interrupts should be disabled by writing a 0 in the corresponding IE bits. – For more details please refer to description of DMA_PM_DS_CONFIG in the DCRs. – The data in the memory area defined by the MEM_DEPTH parameter is always filled in a sequential fashion as in a FIFO, but can be read sequentially or randomly. There can be no slot-memory location correspondence due to the T bit errors in the Manchester decoder. – The memory area above the configured MEM_DEPTH size will always be read as 0. – Irrespective of the configuration, the data can always be randomly read by the CPU from the PMRL/PMRH register.
11 ERROR_SELECT[4]	The ERROR_SELECT bitfield indicates which of the C, E, EM, T, or F error conditions generate an interrupt when the EICR Interrupt Enable bit is set. The individual bits are mapped as {C,E,EM,T,F}. The corresponding error is also latched in the PSI5_EISR. Default: ERROR_SELECT = 11111: Any of C,E,EM,T,or F generate an interrupt. C error CRC Error (C) Bit 20: ERROR_SELECT[4] or C_INT_SEL 0 The C bit does not generate an interrupt. 1 The C bit generates an interrupt.

Table 1133. PSI5_PCCR field descriptions (continued)

Field	Description
12 ERROR_SELECT[3]	Error_Select[3] or E_INT_SEL E error Electrical Error (E) 0 The E bit does not generate an interrupt. 1 The E bit generates an interrupt.
13 ERROR_SELECT[2]	Error_Select[2] or EM_INT_SEL 0 The EM bit does not generate an interrupt. 1 The EM bit generates an interrupt.
14 ERROR_SELECT[1]	Error_Select[1] or T_INT_SEL 0 The T bit does not generate an interrupt. 1 The T bit generates an interrupt.
15 ERROR_SELECT[0]	Error_Select[0] or F_INT_SEL 0 The F bit does not generate an interrupt. 1 The F bit generates an interrupt.
17 GTM_RESET_ASYNC_EN	GTM_RESET_ASYNC_EN 0 Both the assertion and the deassertion of the GTM reset are treated synchronously. Inside the IP the GTM reset is synchronized on the “ipg_clk_psi5”. This can delay the impact of the GTM reset by 1 to 2 system clock(ipg_clk_psi5). Please refer to Figure 1192 for the definition of “ipg_clk_psi5”. 1 Assertion of the GTM reset is treated asynchronously but deassertion is synchronized on the ipg_clk_psi5.
21 DEBUG_EN	This bit allows/prevents the IP from entering the debug mode, whenever the debugger is connected and a breakpoint is encountered by the debugger: 0 The IP never enters the debug mode, even if the debugger is connected and a breakpoint is encountered. It keeps on working normally, as in the functional mode. 1 Whenever the debugger is connected and a breakpoint is encountered, the IP enters the debug mode. In the Debug mode, the DMA read pointers and other status registers that normally get affected by the READ operation remain unaffected.
22 DEBUG_FREEZE_CTRL	0 When the IP enters the Debug mode then it goes into the “Open” mode, i.e., the core of the IP keeps on working normally. In this case, there can be a difference between the value of a particular status bit, which is there at the time Debug mode is entered and the time at which the debugger reads it, since some upcoming events might change the status. The hardware clearing, of course, remains disabled. <i>Note: In the above configuration, the status of registers read through the debugger may be different when entering debug mode and when actually accessing registers at some later point of time.</i> 1 When the IP enters the “Debug mode” then it goes into the “Freeze Mode”. Note that whenever there is a request to enter the freeze mode then the IP enters this mode, ONLY when the Manchester decoder and the Sync Pulse Generator are stopped coherently. This means that before entering the “freeze mode”, if there is any pending reception that is ongoing, then the same is completed first. Simultaneously the “sdout” line of the IP should be at a low level. Once these two conditions are satisfied, the IP enters the Debug Freeze mode. The Time Stamp counters are also halted. In the above configuration, incoming packets could get lost while the Debug mode is active.

Table 1133. PSI5_PCCR field descriptions (continued)

Field	Description
23 SP_TS_CLK _SEL	This bit controls which clock goes to the Sync Pulse and Time Stamp Generator Unit. 0 The 1 MHz clock generated from the CGM goes for clocking the Time Stamp Unit and sync pulse generator. 1 The clock generated from the GTM goes for clocking the Time Stamp Unit and Sync Pulse Generator. <i>Note: The above selection affects ONLY the clock for the Time Stamp Unit and Sync Pulse Generator. The 1 MHz clock to the rest of the logic like the Manchester decoder or the Slot Boundary Counters is still the 1 MHz from the CGM.</i> <i>Note: The clock selected using this bit is called SP_TS_CLK.</i>
26 FAST_CLR _SMC	This bit controls the clearing mechanism of the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits in the GISR. 0 Fast clearing is disabled (clear when written to 1). 1 Fast clearing is enabled. <i>Note: This bit is effective only when DCR[DMA_EN_SF] = 1. When FAST_CLR_SMC = 1 then the IS_NVSM[x], IS_CESM[x], and IS_OWSM[x] bits are automatically cleared upon reading the DSFR message register, as per the slot[x] message read in from the DSFR. When reading directly from the SFR registers, this bit does not affect auto clearing.</i> <i>If FAST_CLR_SMC = 0 then the above bits have to be cleared by a w1c.</i>

Table 1133. PSI5_PCCR field descriptions (continued)

Field	Description
27 FAST_CLR_PSI5	This bit control the clearing mechanism of bits in NDSR (in conf2, conf3 and conf4 modes), EISR (in conf2, conf3 and conf4 modes), and OWSR (in conf2 and conf3 modes). 1 Fast Clearing Enabled 0 Fast Clearing Disables (clear when written to 1) <i>Note: This bit is effective only when DMA_PM_DS_CONFIG = conf2, conf3, or conf4 else this bit has no effect and only software clearing is available. Further, though the OWSR is not directly read by the DMA as a single register, it is cleared in specific modes (when FAST_CLR_PSI5 == 1) as can be seen below.</i> Following are the details in the various modes of the DCR[DMA_PM_DS_CONFIG] bits: – In conf1 mode: This bit has no effect. Reading the DDSR and the DPMR returns a 0. – In conf2 mode: In this case the diagnostic bits (EISR, NDSR) are cleared ONLY when the diagnostic registers appended with the corresponding PSI5 messages are completely read using the DPMR. During the intermediate operation (when the PSI5 message has been read but the diagnostic bits are still pending), the PSI5 message read from the DPMR will not clear these bits. Both of these registers are simultaneously cleared when the corresponding DMA operation is over. However, only those bits are cleared, the corresponding messages of which form the part of the DMA request being serviced. Note that the OWSR bits are cleared upon the corresponding PSI5 message read from the DPMR. Reading the DDSR returns a 0 in this mode. – In conf3 mode: The PSI5 diagnostic register bits (EISR,NDSR) and OWSR are automatically cleared when the corresponding PSI5 message is read from the DPMR. The specific register bits of EISR,NDSR and OWSR, corresponding to each message, are cleared sequentially one by one as the corresponding message is being read by the DMA. Note that the three bits (each of EISR, NDSR, and OWSR) corresponding to a specific location are always cleared simultaneously. Reading the DDSR returns a 0. When reading from the PMRH/PMRL registers, this bit does not have any effect on fast clearing. – In conf4 mode: In this case the diagnostic bits (EISR, NDSR) are cleared as soon as these registers are read through the DDSR. These registers are cleared simultaneously in one go, as soon as the corresponding DMA request has been serviced. Only those bits of these registers are cleared, the messages of which form a part of the DMA request. Note that in this mode the reading of the PSI5 messages from the DMA is not available as the request is being used for reading the diagnostic registers. Reading the DPMR returns a 0. The PSI5 messages can be read only from the PMRH/PMRL register. Hence the OWSR has to be cleared only by w1c. – In all the above modes, when reading from the PMRH/PMRL registers, the FAST_CLR_PSI5 does not have any effect on fast clearing. – Further, In all the above cases if FAST_CLR_PSI5 = 0 then the specific diagnostic bits and the OWSR have to be cleared by w1c.
28 BIT_RATE	This bit selects the receive message bit rate (T bit) for this particular PSI5 Channel, that is, it selects one of the two driven clocks (4 MHz or 6.048 MHz) in CGM. 0 125 Kbit/s bit rate selected (4 MHz clock). 1 189 Kbit/s bit rate selected (6.048 MHz clock).
29 MODE	This bit selects the operating modes. 0 Asynchronous operating mode (Integrated sync pulse generator module is switched off, only RX active). Note that in this mode the sync pulses from the internal sync pulse generator or the GTM are not allowed to be propagated to the output path, which always remains at logic 0. There is no T-bit error in the Asynchronous mode. 1 Synchronous operating modes (Integrated sync pulse generator module is switched on, both TX and RX subblocks active).

Table 1133. PSI5_PCCR field descriptions (continued)

Field	Description
30 PSI5_CH_CONFIG	PSI5 Channel Config mode request. If this bit is set (and PCCR[PSI5_CH_EN] = '1') this particular psi5 channel enters Configuration mode from Disable mode. Default value is 0. User software must program all PSI5 channel parameters before clearing this bit. Once cleared, channel parameters in registers are locked for writing. The values set cannot be changed until this bit is set again after entering the Disable mode 1 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') - PSI5 Channel enters Config mode. Various configuration registers can be programmed in this mode. The only registers NOT writable in the config mode but writable in the Normal mode are the output registers PSI5_DBR and the PSI5_DSR. 0 (If PCCR[PSI5_CH_EN] = '1' and GCR[GLOBAL_DISABLE_REQ] = '0') PSI5 Channel enters Normal mode. Channel parameter registers are locked for writing. This bit can be written in all the modes but writing a "0" in the Normal mode will not change the operation mode of the device. <i>Note: This bit can be written in all modes, but writing a 0 in the Normal mode does not change the operation mode of the device. For more details please see Figure and Table 1129. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.</i>
31 PSI5_CH_EN	PSI5 Channel Enable. If this bit is cleared this particular psi5 channel continues to stay in Disable mode even if GCR[GLOBAL_DISABLE_REQ] = 0. If set, it enters Configuration mode from Disable mode (based on PCCR[PSI5_CH_CONFIG]). Default value is 0. All state machines are disabled. This bit can be written in all modes. 0 PSI5 channel continues in Disable mode. 1 PSI5 channel enabled to enter Config/Normal mode. <i>Note: When PSI5_CH_EN == 0 then the clock enable for that particular channel that goes from the IP, goes to "0" (inactive state). " "The enable for the GTM Clock is not controlled by the IP and should be controlled externally. Do note that when going from Disable to Config mode, the programming of other bits of this register CANNOT be done in the same cycle, as the one in which this bit is being written.</i>

53.3.2.3 DMA Control Register (PSI5_DCR)

Table 1134. PSI5_DCR field descriptions

Field	Description
3–7 DMA_PM_DS_WM[4:0]	0 to 31Valid water mark levels. Value fixed by user software. Since each location has two 32-bit registers hence a total of sixty-four 32-bit words are present. The default and minimum value of dma_pm_ds_wm is '0', i.e., 1 message/Diagnostic bit of 1 location. The maximum value of dma_pm_ds_wm is 31, i.e., the actual watermark = 32 RAM locations. <i>Note:</i> – These bits are ineffective if DMA_PM_DS_CONFIG = conf1. – These bits indicates the number of PSI5 message to be stored in FIFO / number of unread diagnostic bits in the diagnostic registers with a correspondence to the messages in the FIFO, before the corresponding DMA request is asserted. The watermark definition changes depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR as mentioned below. – When DMA_PM_DS_CONFIG = conf2 or conf3 then the watermark refers to the number of new unread PSI5 messages that are stored in the FIFO before a DMA request is asserted. – In conf2 mode of DMA_PM_DS_CONFIG, the number of words to be transferred, set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value + 2 words (for the two 32-bit diagnostic registers). – In conf3, the number of words to be transferred set in the DMA controllers TCD must be set equal to the number of words corresponding to the set water mark value. – When DMA_PM_DS_CONFIG = conf4 then the watermark refers to the number of new unread diagnostic bits in the diagnostic register. In this configuration the PSI5 messages can only be read by the CPU, since the DMA request would cater to reading the diagnostic bits only. – In conf4, the number of words transferred in each DMA request = 2 x 32-bit words (for the two 32-bit diagnostic registers). The water mark however refers to the number of new unread diagnostic bits pertaining to each PSI5 message in the FIFO.
13 IE_DMA_TF_SF	Enable for interrupt, which is generated when DMA transfer finishes for DMA SMC Frame register. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
14 IE_DMA_TF_PM_DS	Enable for Interrupt, which is generated when DMA transfer finishes for PSI5 messages/DMA Diagnostic Status register depending on the DMA_PM_DS_CONFIG bits of the DCR. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
20 IE_DMA_PM_DS_FIFO_FULL	This bit is effective only when the DMA_PM_DS_CONFIG = conf2,conf3 or conf4. It enables the FIFO FULL condition generation interrupt. For the cases that generate these FIFO FULL conditions, please refer to the description of IS_DMA_PM_DS_FIFO_FULL register bit of the DSR. <i>Note: This bit is writable in Config and Normal modes.</i>
21 IE_DMA_SFUF	Enables interrupt when there is underflow in DMA SMC Frame register when DMA is enabled. It is set when the DSFR is read without a valid DMA request, i.e., it is empty. Default value is 0. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>

Table 1134. PSI5_DCR field descriptions (continued)

Field	Description
23 IE_DMA_PM_DS_UF	Enables interrupt when there is underflow in DMA PSI5 message register when DMA is enabled. Default value is 0. For the details as to when this underflow occurs, please refer to the details of IS_DMA_PM_DS_UF bit details of the DSR. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
29 DMA_EN_SF	Enable DMA request for SMC Frame Data 0 DMA for SMC frame is disabled. The six dedicated 1-1 slot corresponding SMC registers can only be read by the CPU through the SFR. Reading the DSFRs returns 0. 1 DMA for SMC frame is enabled. The six dedicated slot corresponding SMC registers can be read by reading the DSFR successively. In the DMA mode the six registers are read in a round robin fashion as explained in the DSFR details. Reading directly through the SFR registers is still available.
30–31 DMA_PM_DS_CONFIG	These bits define how the PSI5 messages are stored in the MEM_DEPTH memory area and the associated diagnostic bits (EISR, NDSR) are transferred. 00 conf1 The DMA request is disabled. In this mode, only the interrupts can be used for indicating that data transfer is required. 01 conf2 After transferring the “dma_pm_ds_wm” number of PSI5 messages, there will be two additional 32-bit transfers in which the NDSR and the EISR registers are sequentially transferred through the DPMR registers by using DMA. 10 conf3 “dma_pm_ds_wm” number of PSI5 messages is transferred in each DMA request. The DMA read is through the DPMR registers. 11 conf4 Only the diagnostic bits are transferred through the DDSR. The DMA read is through the DDSR registers. The DPMR, DDSR, and DSFR registers should be used for DMA access and the PMRH/PMRL, NDSR, EISR, and OWSR registers should be used for CPU access. <i>Note: For more details please see the description of the DCR[DMA_PM_DS_WM] bits.</i> <i>When DMA_PM_DS_CONFIG bits = conf2 or conf3 and if the CPU and the DMA are simultaneously used for reading the PSI5 messages, then in the course of reading the messages it is possible that there can be an overflow, though some intermediate locations, which have been read by the CPU, are empty. This will occur because the DMA access is made independent of the CPU access. The DMA logic would never know that the CPU has already read a message that was scheduled to be read by the DMA.</i> <i>Whenever the DMA is used for reading the PSI5 message (conf2/conf3) modes then though the CPU can read the messages in parallel through the PMRH/PMRL registers, still for the purpose of setting the Overwrite/Overflow bits only a read from the DMA through the popup registers (DPMR) would be treated as valid read. This will also be true for the SMC messages when accessed simultaneously by the CPU/DMA.</i>

Figure 1130 shows the DMA Status Register.

Table 1135. PSI5_DSR field descriptions

Field	Description
13 IS_DMA_TF_SF	This flag is set when DMA transfer finishes for DMA SMC Frame register.
14 IS_DMA_TF_PM_DS	This flag is set when DMA transfer finishes. For the various configurations of this request please refer to the descriptions of the DMA_PM_DS_CONFIG bits in the DCR. This flag is cleared by w1c.

Table 1135. PSI5_DSR field descriptions (continued)

Field	Description
20 IS_DMA_PM_DS_FIFO_FULL	Interrupt Status when there is FIFO FULL corresponding to the DMA request ipd_psi5_dma_req_pm_ds. The FIFO FULL scenarios are detailed below with respect to the various settings of the DMA_PM_DS_CONFIG bit. conf1: FIFO FULL disabled conf2 and conf3: FIFO FULL occurs when all the memory locations become full in the PSI5 message FIFO. It indicates that without any read, any new upcoming message will now overwrite the existing messages and set the overwrite bits. This bit is cleared either by w1c or upon a PSI5 message read depending on the FAST_CLR_PSI5 bit. conf4: FIFO FULL occurs when there is a “REGISTER FULL” in the Diagnostic registers. FIFO FULL here means that the diagnostic registers contain 32 unread diagnostic bits. A new message starts changing the status of the diagnostic bits. In this configuration it is necessary to read the diagnostic bits through the DMA using the DDSR in order to prevent FIFO FULL. Of course the diagnostic registers NDSR/EISR can be read any time by the CPU, but to prevent FIFO FULL they HAVE to be read through the DDSR registers only. Also in this mode the PSI5 messages DONT contribute to the FIFO FULL. The PSI5 messages have to be read by the CPU using the PMRH/PMRL registers in order to prevent the overwrite bits from being set in the OWSR. In this mode the OWSR bits are NOT automatically cleared upon the PSI5 message read since the PSI5 message has to be read by the PMRH/PMRL register and NOT though the DPMR. The OWSR bits have to be cleared by a w1c. Reading the DPMR returns a 0 in this mode. This bit is cleared by a w1c. 0 No FIFO full. 1 FIFO full has occurred
21 IS_DMA_SFUF	SMC Frame DMA underflow: This happens when the DSFR has been read without a proper DMA request being asserted. The DSFR is empty and it is read. This bit is cleared by a w1c. 0 No underflow has occurred. 1 Underflow has occurred.
23 IS_DMA_PM_DS_UF	Depending on the DMA_PM_DS_CONFIG bits following is the underflow conditions: Default value is 0. conf1: underflow disabled conf2 and conf3: Underflow happens when the software reads the PSI5 message FIFO though the DPMR, beyond the available messages (empty area). conf4: Underflow happens when the diagnostic registers are read through the DDSR without a valid DMA request and the DDSR contains no new data. 0 No underflow has occurred. 1 Underflow has occurred. The bits are cleared by a w1c.

53.3.2.5 General Interrupt Control Register (PSI5_GICR)

The General Interrupt Control Register (PSI5_GICR) contains the bits for controlling the SMC message related interrupts, interrupts related to ECU-to-sensor communication, and interrupts to the Time Stamp.

Figure 1131. General Interrupt Control Register (PSI5_GICR)

Table 1136. PSI5_GICR field descriptions

Field	Description
2–7 IE_CESM[6:1]	Interrupt request when received SMC frame in corresponding slot has CRC failure (CRC recalculation on SMC). 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: These bits are writable in Config and Normal modes.</i>
8 IE_STS	Interrupt request enabled when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
9 IE_DTS	Interrupt request enabled when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
10 IE_DSROW	Interrupt request enabled when system tries to overwrite on Data Shift register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
11 IE_BROW	Interrupt request enabled when system tries to overwrite on buffer register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
12 IE_PROW	Interrupt request enabled when system tries to overwrite on Preparation register when it is not ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>

Table 1136. PSI5_GICR field descriptions (continued)

Field	Description
13 IE_DSRR	Interrupt request enabled when Data Shift Register is ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
14 IE_BRR	Interrupt request enabled when buffer Register is ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
15 IE_PRR	Interrupt request enabled when Preparation Register ready to accept new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: This bit is writable in Config and Normal modes.</i>
18–23 IE_OWSM[6:1]	Interrupt request enable for the SMC message Overwrite bits. The interrupt for SMC message overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten the overwrite bit gets set. <i>Note: These bits are writable in Config and Normal modes.</i>
26–31 IE_NVSM[6:1]	Interrupt request enabled when any new valid SMC message (fault free) is received in SFR[i]{i:0 to 5}, i.e., during slot1 to slot6. This interrupt is generated only when corresponding IS_NVSMS[5:0] is set. For each bit position, the corresponding request is enabled as follows: 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: These bits are writable in Config and Normal modes.</i>

53.3.2.6 New Data Interrupt Control Register (PSI5_NDICR)

The New Data Interrupt Control Register (PSI5_NDICR) contains the interrupt enable bits related to a new PSI5 message arrival, in the corresponding PSI5 message buffer location.

Figure 1132. New Data Interrupt Control Register (PSI5_NDICR)

Address: Base + 0x0018 + (0x1C0 × channel)

Access: User read/write

Table 1137. PSI5_NDICR field descriptions

Field	Description
0–31 IE_ND[31:0]	Interrupt request enabled when any new message (fault-free/with fault) is received in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt is generated only when corresponding RAM buffer Ready with new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: These bits are writable in Config and Normal modes.</i>

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

53.3.2.7 Overwrite Interrupt Control Register (PSI5_OWICR)

The Overwrite Interrupt Control Register (PSI5_OWICR) is related to the generation of the overwrite interrupts. The overwrite interrupt is generated when the unread PSI5 message in a particular RAM location is overwritten by another PSI5 message.

Figure 1133. Overwrite Interrupt Control Register (PSI5_OWICR)

Address: Base + 0x001C + (0x1C0 × channel)

Access: User read/write

Table 1138. PSI5_OWICR field descriptions

Field	Description
0–31 IE_OW[31:0]	Interrupt request enabled when any new message overwrites the old unread PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31], This interrupt generated only when corresponding RAM buffer Ready with new data. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: These bits are writable in Config and Normal modes.</i>

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

53.3.2.8 Error Interrupt Control Register (PSI5_EICR)

[Figure 1134](#) shows the Error Interrupt Control Register.

Figure 1134. Error Interrupt Control Register (PSI5_EICR)

Address: Base + 0x0020 + (0x1C0 × channel) Access: User read/write

Table 1139. PSI5_EICR field descriptions

Field	Description
0–31 IE_ERROR [31:0]	Interrupt request enabled when any/all of the error conditions C, E, EM, T, or F is observed in a PSI5 message in the RAM buffer Register 'x' location [x: 0 to 31]. This interrupt is generated only when the corresponding RAM buffer is Ready with new data. Which error condition (any of C, E, EM, T, or F) generates the interrupt is selectable by the PCCR[ERROR_SELECT] field. If all are selected, then which of C,E,EM,T or F is set can be isolated by reading the corresponding received message. 0 Interrupt is disabled. 1 Interrupt is enabled. <i>Note: These bits are writable in Config and Normal modes.</i>

Note: Depending on the value of MEM_DEPTH in the PCCR, only the corresponding diagnostic bits are set in this register.

53.3.2.9 General Interrupt Status Register (PSI5_GISR)

The General Interrupt Status Register (PSI5_GISR) contains the status bits related to SMC messages, ECU-to-sensor communication, and the Time Stamp.

Figure 1135. General Interrupt Status Register (PSI5_GISR)

Address: Base + 0x0024 + (0x1C0 × channel)

Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1140. PSI5_GISR field descriptions

Field	Description
2–7 IS_CESM[6:1]	These flags are set when the received SMC frame in the corresponding slot has a CRC failure (CRC recalculation on SMC). These bits are automatically cleared upon message read, when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1.
8 IS_STS	This Interrupt flag is set when the Sync Pulse Triggered Time Stamp value is refreshed on STSRR.
9 IS_DTS	This Interrupt flag is set when the Data Start sequence Triggered Time Stamp value is refreshed on DTSRR.
10 IS_DSROW	This flag is set when the system tries to overwrite on Data Shift register when it is not ready to accept new data.
11 IS_BROW	This flag is set when the system tries to overwrite on buffer register when it is not ready to accept new data.
12 IS_PROW	This flag is set when the system tries to overwrite on Preparation register when it is not ready to accept new data.
13 DSR_RDY ⁽¹⁾	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Shift register is ready to receive new data from the system bus side or the Data Buffer register. When “0” it indicates that there is a ongoing command transmission of the data in DSR, or the CPU has done a “w1c” to this bit leading to the new command transmission. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_DSROW] bit gets set. A write to PSI5_DOBCCR[DSR_RST] will abort the current command transmission and make the DSR_RDY as “1”. Control Bit Action: When a “w1c” is done to this register bit, and PSI5_DOBCCR[SW_READY] == 1, then it indicates to the IP that the data in DSR is valid and is to be used for command shifting. This procedure is used when the data is written by the CPU to DSR directly skipping the DBR. For detailed action of this bit please refer to Section 53.4.3.4, Data transmission.

Table 1140. PSI5_GISR field descriptions (continued)

Field	Description
14 DBR_RDY ⁽²⁾	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Buffer register is ready to receive new data from the system bus side or the Data Preparation register. When “0” it indicates that there is a ongoing shift of the data from the DPR to the DBR, or the CPU has done a “w1c” to this bit. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_BROW] bit gets set. A write to PSI5_DOBCCR[DBR_RST] will abort the current data transaction in DBR and make the DBR_RDY as “1”. Control Bit Action: When a “w1c” is done to this register bit, then it indicates to the IP that the data in DBR is valid and is to be used for shifting to DSR. This procedure is used when the data is written by the CPU to DBR directly skipping the DPR. For detailed action of this bit please refer to Section 53.4.3.4, Data transmission.
15 DPR_RDY ⁽³⁾	This bit acts both as a status and a control bit. Status bit Action: When “1” it indicates that the Data Preparation register is ready to receive new data from the system bus side. When “0” it indicates that there is a ongoing processing of the data in DPR or there is a data shift ongoing from the DPR to the DBR, or the CPU has done a “w1c” to this bit. In this case any write by the CPU to this register will be rejected and the PSI5_GISR[IS_PROW] bit gets set. When PSI5_DOBCCR[CMD_TYPE] == “7” then this bit remains at value “0”. Control Bit Action: When a “w1c” is done to this register bit, then it indicates to the IP that the data in DPR is valid and is to be used for processing and shifting to DBR. For detailed action of this bit please refer to Section 53.4.3.4, Data transmission.
18–23 IS_OWSM[6:1]	Status for the SMC message overwrite bits. Each of the 6 locations correspond to the SMC message pertaining to each SFR[x] register, x = 1 to 6. These bits are automatically cleared upon message read when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1.
26–31 IS_NVSM[6:1]	These flags are set when corresponding SFR[i] receives and is ready (to read) with new valid SMC message. These bits are automatically cleared upon message read, when the FAST_CLR_SMC = 1 and the DMA_EN_SF = 1.

1. For these register bits individual “bit setting” commands should not be used. Rather, the normal register read/write commands should be used.
2. For these register bits individual “bit setting” commands should not be used. Rather, the normal register read/write commands should be used.
3. For these register bits individual “bit setting” commands should not be used. Rather, the normal register read/write commands should be used.

53.3.2.10 DMA PSI5 Message Register (PSI5_DPMR)

[Figure 1136](#) shows the DMA PSI5 Message Register.

Figure 1136. DMA PSI5 Message Register (PSI5_DPMR)

Address: Base + 0x0028 + (0x1C0 × channel)

Access: User read/write

Table 1141. PSI5_DPMR field descriptions

Field	Description
0–31 PSI5_RXDATA [31:0]	PSI5_RXDATA[31:0] This popup register contain the PMRL[31:0] data followed by the PMRH[31:0] data for each of the FIFO locations, when the FIFO is read by the DMA. It would require two 32-bit IPS access to read one PSI5 Message. For each of the locations, the DATA is pushed sequentially until all the data corresponding to the programmed watermark is complete, after which the DMA request is deasserted. The depth of the FIFO is 32x64. This popup register can be used differently based on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. When DMA_PM_DS_CONFIG=conf2 then it pops the PSI5 message, followed by NDSR, followed by EISR. When DMA_PM_DS_CONFIG= conf3, it pops only the PSI5 messages. When DMA_PM_DS_CONFIG=conf4, it pops the NDSR followed by EISR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the Section 53.3.2.2, PSI5 Channel Control Register (PSI5_PCCR), Section 53.3.2.3, DMA Control Register (PSI5_DCR), and Section 53.3.2.4, DMA Status Register (PSI5_DSR).

53.3.2.11 DMA SMC Frame Register (PSI5_DSFR)

Figure 1137 shows the DMA SMC Frame Register.

Figure 1137. DMA SMC Frame Register (PSI5_DSFR)

Address: Base + 0x002C + (0x1C0 × channel)

Access: User read/write

Table 1142. PSI5_DSFR field descriptions

Field	Description
0–31 SMC_RXDATA[31:0]	When the DMA_EN_SF = 1, then the six SFR registers are searched in a round robin fashion for the reception of the complete SMC data. The DMA request is asserted as soon as the first encountered SFR has a complete SMC frame. This request remains asserted until all the registers that have pending data, have transferred the data through the DMA. Each other SFR is a 32-bit register. This register is a reflection of the location pointed to by the DMA read pointer.

53.3.2.12 DMA Diagnostic Status Register (PSI5_DDSDR)

Figure 1138 show the DMA Diagnostic Status Register.

Figure 1138. DMA Diagnostic Status Register (PSI5_DDSDR)

Address: Base + 0x0030 + (0x1C0 × channel)

Access: User read/write

Table 1143. PSI5_DDSR field descriptions

Field	Description
0–31 DDS[31:0]	This register maps each of the individual Diagnostic registers (in the order NDSR, EISR) depending on the configuration of the DMA_PM_DS_CONFIG bits in the DCR. This register is a reflection of the location, pointed to by the DMA read pointer. For more details please refer to the Section 53.3.2.2, PSI5 Channel Control Register (PSI5_PCCR) , Section 53.3.2.3, DMA Control Register (PSI5_DCR) and Section 53.3.2.4, DMA Status Register (PSI5_DSR) .

Note: No FIFO is implemented for diagnostic registers. They are two 32-bit registers addressable by either the CPU (reading NDSR or EISR directly) or the DMA (reading the DDSR successively).

53.3.2.13 PSI5 Message Receive Register Low (PSI5_PMRRL)

[Figure 1139](#) shows the PSI5 Message Receive Register Low.

Figure 1139. PSI5 Message Receive Register Low (PSI5_PMRRL)

Address: Base + 0x0034 + (0x1C0 × channel)

Access: User read/write

Table 1144. PSI5_PMRRL field description

Field	Description
0-27 DATA_REGION[0:27]	These are application-specific optional bits + data payload of received message. See Section 53.4.2.1, Reception of data frames for more details. The data is left-aligned, i.e., Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits (n: $8 \leq n \leq 28$). If $n < 28$ remaining bit positions are filled with '0's, i.e., between last received bit and CRC field.
28–30 CRC[2:0]	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

53.3.2.14 PSI5 Message Receive Register High (PSI5_PMRRH)

Figure 1140 shows the PSI5 Message Receive Register High.

Figure 1140. PSI5 Message Receive Register High (PSI5_PMRRH)

Table 1145. PSI5_PMRRH field descriptions

Field	Description
0 Reserved	This bit is reserved.
1 F	This represents that NO frame was received in the corresponding configured slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0,M1), that is, at least one bit is absent during the T bit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This bit indicates electrical error, i.e., at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1, and start fields. 1 Electrical error in fields other than M0, M1, and start fields.
4 T	This bit indicates timing error, i.e., frame has started in an unconfigured slot, spread across two slots, started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.

Table 1145. PSI5_PMRRH field descriptions (continued)

Field	Description
5–7 Slot Counter[2:0]	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. For asynchronous modes the slot counter has a fixed value of “1”. The six slots are numbered as Slot1, Slot2,...Slot6.
8–31 Time Stamp Value[23:0]	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_SnFCR). In other words these bits contain either the start bit(S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where “F” bit has been set; the value of the Time Stamp appended to the message is “0”. It is possible to reset the time stamp counter by asserting to “1” the “gtm_reset” signal from the GTM.

Note: Any new PSI5 message is always stored in the PSI5 receive register (PMRRL/PMRRH). In parallel it is also stored in the RAM registers in a sequential manner like in a Ring Buffer. When a new message comes it would always overwrite the data in the PSI5 receive register. But the original message would still be available in the RAM register provided all locations in the RAM registers are not full, and an overwrite has not occurred.

53.3.2.15 PSI5 Message Register Low *i* (PSI5_PMRL*i*) {*i*: 0 to 31}

Table 1146. PSI5_PMRLn field descriptions

Field	Description
0–27 Data Region[0:27]	These are application-specific optional bits + data payload of received message. See Section 53.4.2.1, Reception of data frames for more details. The data is left-aligned, i.e., Data Region[0]/D0 corresponds to first received bit of the PSI5 message after Start sequence detection and Data Region[n]/D'n' corresponds to successive bits up to expected number of bits ($n: 8 \leq n \leq 28$). If $n < 28$ remaining bit positions are filled with '0's, i.e., between last received bit and CRC field.
28-30 CRC[2:0]/P	This field represents CRC/Parity value of the data. When parity configuration is selected in the S[1-6]FCR registers, the CRC[2] bits denotes the parity.
31 C	This bit will be set if CRC/P recalculation return an Error.

53.3.2.16 PSI5 Message Register High *i* (PSI5_PMRHi) {i: 0 to 31}

Table 1147. PSI5_PMRHn field descriptions

Field	Description
0 O	This bit carries the same information as OWSR, but appended here for each message separately. This bit is set when the current message (which is being read) has overwritten some previous unread message. Note that, if the corresponding location in the OWSR has been cleared or has been set by the SOWSR, then the same will be reflected in the message stored in the corresponding RAM location as well.
1 F	This represents that NO frame was received in corresponding configured Slot. 0 Frame was received in the corresponding configured slot. 1 No frame was received (F bit error).

Table 1147. PSI5_PMRHn field descriptions (continued)

Field	Description
2 EM	This bit indicates electrical error in the PSI5 Message at bits corresponding to Serial Messaging Channel (M0, M1), i.e., at least one bit is absent during the Tbit period. 0 No electrical error in M0, M1 fields. 1 Electrical error in M0, M1 fields.
3 E	This Bit Indicates Electrical Error, i.e., at least one bit is absent during the Tbit period (except M0 and M1 bits and the start bits). 0 No electrical error in fields other than M0, M1 and start fields. 1 Electrical error in fields other than M0, M1 and start fields.
4 T	This bit indicates timing error, i.e., frame has started in an unconfigured slot or it has spread across two slots or it has started before the first configured slot. 0 No timing error in the corresponding slot. 1 Timing error in the corresponding slot.
5–7 Slot Counter[2:0]	This value indicates the slot number in which this frame was received. More specifically, it indicates in which slot the start bits of the frame have been detected. If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. For asynchronous modes the slot counter has a fixed value of “1”. The six slots are numbered as Slot1, Slot2,...Slot6.
8–31 Time Stamp Value[23:0]	This is 24-bit Time Stamp value appended to Received message as soon as start bits are detected. This time stamp is captured at rising edge of S0 and stored at the rising edge of S1. The specific value that is appended can be programmed by setting the TS_CAPT bit in the Slot n Frame Configuration Register (PSI5_SnFCR). In other words these bits contain either the start bit (S0) captured time stamp or the SYNC pulse captured time stamp, dependant on TS_CAPT bit. Note that in messages where “F” bit has been set; the value of the Time Stamp appended to the message is “0”. It is possible to reset the time stamp counter by asserting to “1” the “gtm_reset” signal from the GTM.

Table 1148. PSI5_SFR n field descriptions

Field	Description
31–29 SLOT_NO	This indicates in which slot this SMC frame was received. Note that here the slot number refers to the slot in which all the re-arranged PSI5 messages (from which the M0,M1 bits have been extracted) are supposed to have occurred after the correct PSI5 message placement and Timing corrections have been performed. For SFR[1], slot_no = 1; For SFR[2], slot_no = 2; For SFR[3], slot_no = 3; For SFR[4], slot_no = 4; For SFR[5], slot_no = 5; For SFR[6], slot_no = 6;
3 CER	CRC Error 0 The present data has no CRC error. 1 The present data has a CRC error.

Table 1148. PSI5_SFRn field descriptions (continued)

Field	Description
4 OW	Overwrite status 0 The present data was already read when new message arrived. 1 New message has overwritten the previous unread message. <i>Note: If the corresponding SOWSM bits in the SSESr have been set or the OWSM bits in the GISR have been cleared, then the same will be reflected in the message stored in the corresponding RAM location as well. The overwrite occurs when any unread SMC message in a particular SMC slot register gets overwritten by a new SMC message of that particular slot. Even if the SMC message has a CRC error, still if it is unread and is overwritten, the overwrite bit gets set.</i>
5-10 CRC	6-bit CRC for slow serial message
11 C	Configuration bit 0 12-bit data and 8-bit message ID. 1 16-bit data and 4-bit message ID.
12-15 ID[7:4]/ID[3:0]	Message ID: If C = '0' indicates ID[7:4], if C = '1' indicates ID[3:0].
16-19 ID[3:0]/DATA[15:12]	Message ID/DATA: If C = '0' indicates ID[3:0], if C = '1' indicates DATA[15:12].
20-31 DATA[11:0]	DATA payload

Note: Six dedicated 32-bit SFR[x] registers for SMC are available with a 1-1 slot correspondence. These can be read by either the CPU or the DMA (when DMA_EN_SF = 1).

- No FIFO for SMC frame is available. Six 32-bit registers are available in the address space, which can be accessed by either the DMA (using the DSFR) or the CPU (using the six SFR registers), depending on the setting of the DMA_EN_SMC bit.

Field	Description
0–31 NDS[31:0]	New Data Status flags for PSI5 Messages corresponding to each PSI5 MB locations. These bits are set when a new Message arrives, i.e., faulty or non faulty in corresponding PSI5 MB location These bits can be cleared by w1c or the fast clearing. Please refer to PCCR, DCR and DSR registers for more information. Also, these bits can be set independent by writing in SNDR.

53.3.2.19 Overwrite Status Register (PSI5_OWSR)

Table 1155. PSI5_SSESR field description

Field	Description
2–7 SCESM[6:1]	Sets IS_CESM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_CESM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. <i>Note: These bits are writable in Config and Normal modes.</i>
18–23 SOWSM[6:1]	Sets IS_OWSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_OWSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. <i>Note: These bits are writable in Config and Normal modes.</i>
26–31 SNVSM[6:1]	Sets IS_NVSM Status flags for SMC Messages corresponding to each SMC MB locations. The corresponding IS_NVSM Flags can be set by writing to corresponding bits in this registers. This register is required for IP testing purposes (testing of Error Conditions through software). These bits can SET the status flags in parallel to the hardware events and are used for test purpose. These registers are one-shot and would always be read as '0'. <i>Note: This bit is writable in Config and Normal modes.</i>

53.3.2.25 Sync Time Stamp Read Register (PSI5_STSR)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1157. DTSRR field descriptions

Field	Description
5–7 SLOT_COUNT ER[2:0]	3-bit Slot Counter, which corresponds to the slot for which the DTSRR contains the Time Stamp. The slot_counter contains the slot in which the start bits of this frame was captured (after successful detection of S1). If the start bits get detected before the start boundary of Slot1, then the slot counter has a value of “0”. The slot counter is automatically incremented at each slot boundary irrespective of whether a message is received or not. In case of asynchronous mode, the slot counter has a fixed value of “1”.
8–15 DTSV[23:16]	Data Time Stamp Value[23:0] Whenever a valid sequence of the start bits (S0,S1) is detected, the value of the Time Stamp counter captured at the rising edge of the S0 is stored in this register at the rising edge of S1.

Note: If S0 and S1 are detected in different slots then the Time Stamp value and the Slot Counter, both will correspond to the first slot (S0)

53.3.2.27 Slot n Frame Configuration Register (PSI5_SnFCR)

Figure 1153 shows the Slot n Frame Configuration Register.

Figure 1153. Slot n Frame Configuration Register (PSI5_SnFCR)

Table 1158. PSI5_SnFCR field descriptions

Field	Description
13 SLOT_EN	0 This particular slot is disabled, i.e., not in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) have no effect. 1 This particular slot is enabled, i.e., is in use and corresponding configuration bits (as defined by other bits of this PSI5_SnFCR) are applicable.
14 TS_CAPT	0 Time stamp value captured at rising edge of S0 and stored Start sequence first edge. 1 Time stamp value captured at corresponding Tsync pulse (posedge) and stored with corresponding slot PSI5 message.

Table 1158. PSI5_SnFCR field descriptions (continued)

Field	Description
16 SMCL	Serial Messaging Channel field 0 Serial Messaging Channel (optional) not present on Rx Message during Time Slot 'n' 12-bit{M1,M0} Serial Messaging Channel present on Rx Message during Time Slot 'n' This field is used to enable the detection of start sequence of SMC frame on particular slot. Detection is not done if this field is '0'.
26–30 DRL	Data Region Length[4:0] This field represents Length of Data region (including Frame Control, Status, Data payload1&2 regions and optional messaging bits M0,M1) in Rx Message during Time Slot 'n' 00000-00111 Invalid 01000 8 bit long data region 01001 9 bit long data region 01010 10 bit long data region 11011 127 bit long data region 11100 28 bit long data region 11101-11111 Invalid
31 CRC/P	0 3 bit CRC[2:0] present on Rx Message during Time Slot 'n' 1 1 bit Parity field present on Rx Message during Time Slot 'n'

Note: In Asynchronous mode, the PSI5_S1FCR register has to be programmed for controlling the various parameters pertaining to the message received. The other registers PSI5_S[2-6]FCR have no effect in the asynchronous mode.

53.3.2.28 Slot *n* Start Boundary Register (PSI5_SnSBR)

Figure 1154 shows the Slot *n* Start Boundary Register (PSI5_SnSBR).

Total of six registers for each of the six slots. These are S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Here *n* = 1 to 6 corresponding to each of the six slots.

Figure 1154. Slot *n* Start Boundary Register (PSI5_SnSBR)

Address: (0x0008+0x1C0*chnl)+0x0188 + (n-1)*0002

Access: User read/write

Table 1159. PSI5_SnSBR field descriptions

Field	Description
0–15 SnSBT[14:0]	Slot <i>n</i> Start Boundary Time This field specifies the time in intervals of 1 μs, occurring after the <i>rising edge</i> of the timing sync pulse, at which the slot <i>n</i> should start. <i>n</i> = 1 to 6 dedicated for each of the six slots.

53.3.2.29 Slot *n* End Boundary Register (PSI5_*Sn*EBR)

Figure 1154 shows the Slot *n* Start Boundary Register (PSI5_*Sn*SBR).

Slot *n* End Boundary register is a **single register**, which can be programmed to define the “end” of the *n*th slot. The *n* can be defined in the SLOT_NO field of this register.

There are seven boundary registers for the six slots. Six of these registers (S1SBR, S2SBR, S3SBR+, S4SBR, S5SBR, and S6SBR) are used to define the start of each of the six slots.

The seventh register *Sn*EBR (Slot *n* End Boundary register) defines the end of the *n*th slot. The *n* is programmed in the slot_no field of this register.

The number of slots would automatically be available from the *Sn*EBR. The *Sn*EBR contains the slot number of the last slot and the end boundary of the same. Each slot can separately be enabled or disabled by using the slot_en bit in the *Sn*FCR. When the start slot boundaries are properly defined in the *Sn*SBR (Slot *n* Start Boundary Register) register but the slot_en bit = 0 in the corresponding *Sn*FCR (Slot *n* Frame Configuration register) register, then the corresponding slot is treated as “available” but “unconfigured.” For such a slot the data/diagnostic bits all remain 0. *The “T” bit will, however, get set if a message that was supposed to come in a configured slot actually arrives in an unconfigured slot. Note that the various parameters like the Data length/CRC configuration and so on are valid ONLY for the configured slots.* Even when sampling a message in an unconfigured slot, these parameters would be taken from the previous/next configured slot only. It is assumed that no data would be sent in an unconfigured slot. If a data is received in this unconfigured slot it would never be treated as belonging to the unconfigured slot. As a special case if “S0” and “S1” are detected in different slots then a T-bit error is set.

Figure 1155. Slot *n* End Boundary Register (PSI5_*Sn*EBR)

Address: (0x0008+0x1C0*chnl)+0x0194

Table 1160. PSI5_SnEBR field descriptions

Field	Description
13–15 SLOT_NO[2:0]	The field indicates the Slot number{1–6} for which Slot End Boundary Time is defined. Any value other than 1–6 is defaulted to 0. A value 0 here would mean that the Manchester decoder would not sample any slots. This slot number also defines the number of slots that the IP assumes to exist between 2 sync pulses.
17–31 SnEBT[14:0]	Slot <i>n</i> End Boundary Time. This field specifies the time in intervals of 1 μ s, occurring after the rising edge of timing sync pulse, at which the slot <i>n</i> should end.

Note: The start slot boundaries in the SnSBR should be correctly programmed. If this is not done, the correct operation cannot be guaranteed. Slots occurring after the slot_no value programmed in the SnEBR are treated as being unavailable (that is, the data in all the slots occurring after the SnEBR is rejected by the Manchester decoder).

Following are the examples:

- If only three slots are required between two sync pulses, program S1SBR, S2SBR, and S3SBR with the correct value of the start boundaries of the three slots and program slot_no = 3 in the SnEBR and define the end boundary of the third slot in SnEBR. The design ignores slots 4, 5, and 6.
- For six slots, the required programming would be: program the start of each of the six slots in S1SBR, S2SBR, S3SBR, S4SBR, S5SBR, and S6SBR. Then program the end of the sixth slot in the SnEBR by putting slot_no = 6 and define the end boundary of the sixth slot in SnEBR.

53.3.2.30 Data Output Block Configuration Register (PSI5_DOBCCR)

Figure 1156 shows the Data Output Block Configuration Register.

Figure 1156. Data Output Block Configuration Register (PSI5_DOBCCR)

Address: Base + 0x01A0 + (0x1C0 × channel)

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	DATA_LENGTH[5:0]					0	0	CMD_TYPE[2:0]				DEFAULT_SYNC	GTM_TRIG_SEL	SPULSE_SEL	OP_SEL	SW_READY
W						DBR_RST	DSR_RST									
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1161. PSI5_DOBCCR field descriptions

Field	Description
0-5 DATA_LENGTH[5:0]	Can take on values from 0 to 63 corresponding to 1bit to 64bit non standard length commands. When PSI5_DOBCCR[CMD_TYPE] == 7(Non Standard), then this field controls the length of command that can be written to the DBR and the DSR registers, else the value in this field is ignored. This when DATA_LENGTH = 0 then the length of the command that can be written to DSR and the DBR is 1, when DATA_LENGTH=1 then the length of the command that can be written to DSR and the DBR is 2 and so on until a maximum of 64-bit length command when DATA_LENGTH = 63. Note that the length of the command that is programmed by using this field, is also equal to the length of the command that shifts out of the DSR register. In other words, it is equal to the number of bits, that shift out of DSR register once the DSR_RDY goes low. After these many shifts have happened, then the value corresponding to "DEFAULT_SYNC" starts getting shifted out and DSR_RDY goes as "1".
6 DBR_RST	This is to reset and reject current content to Data Buffer Register. When this bit is written as "1" then the contents of the DBR are reset to all "0s" (if DEFAULT_SYNC= 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DBR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.
7 DSR_RST	This is to reset and reject current content to Data Shift Register. When this bit is written as "1" then the contents of the DSR are reset to all "0s" (if DEFAULT_SYNC= 0) or all "1s" (if DEFAULT_SYNC == 1). As soon as content is reset the DSR would be ready for new data. Reading this bit would always return a "0". Writable to 1 in one shot. This bit is writable in the CONFIG and the Normal modes.

Table 1161. PSI5_DOBCCR field descriptions (continued)

Field	Description			
8-10 CMD_TYPE[2:0]	These 3 bits indicate the type of command that needs to be transmitted during the ECU to sensor communication. Following is a brief description of the same:			
	CMD_TYPE	PSI5 Frame	Effect on registers	Writeable Register lengths
	"000" - 0	Short Frame with 31 "1s" as the start condition*	Command can be written to DPR for auto calculation of stuff/start/CRC bits. Can always be overwritten in DSR/DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	6 bits in DPR 15 bits** in DBR/DSR.
	"001" - 1	Short Frame with 5 "0s" as the start condition*	-do-	-do-
	"010" - 2	Long Frame with 31 "1s" as the start condition*	-do-	16 bits in DPR. 29 bits** in DBR/DSR.
	"011" - 3	Long Frame with 5 "0s" as the start condition*	-do-	-do-
	"100" - 4	X-Long Frame with 31 "1s" as the start condition*	-do-	22 bits in DPR. 37 bits** in DBR/DSR
	"101" - 5	X-Long Frame with 5 "0s" as the start condition*.	-do-	-do-
	"110" - 6	XX-Long	-do-	24 bits in DPR. 43 bits** in DBR/DSR
	"111" - 7	Non Standard Length.	Command can only be written to DSR and DBR registers provided DSR_RDY == 1 or DBR_RDY == 1 respectively	Programmable from 1 to 64 bits in DBR/DSR, depending on the value of PSI5_DOBCCR[DATA_LENGTH] field.
* The start condition (31 "1s" or 5 "0s") is automatically taken care by the hardware and should NOT be written to the registers as part of the command; neither is this visible in any register. ** This is also the length of the command, that will be shifted out during the ECU to Sensor communication, irrespective of how many "actual" number of bits are written to DBR/DSR.				

Table 1161. PSI5_DOBCCR field descriptions (continued)

Field	Description
11 DEFAULT_SYNC	When this bit is set to “0” then the default value of DSR and DBR registers are all “0s”; when this bit is set to 1 then the default value of DBR and DSR registers are all “1s”. This value is used as the value of the default sync pulses shifted at the output path when the DSR_RDY == 1.
12 GTM_TRIG_SEL	GTM event triggered/internal sync pulse generator selection as shift clock for the DSR. 1GTM event shift triggered 0Internal sync pulse generator shift triggered
13 SP_PULSE_SEL	Selects the source for the short pulse PWM module: 1 SP module directly gets input from the GTM_event/internal sync pulse generator 0 SP module gets the data from the DSR
14 OP_SEL	This bit selects the driving source of the “ipp_do_psi5_sdout” port. 0 The sync pulse generator select as per the PSI5_DOBCCR[GTM_TRIG_SEL] 1 PWM output
15 SW_READY	When this bit is written to 1 the transfer from DBR to DSR automatically happens as soon as DSR_RDY becomes 1. When this bit is kept to 0 then the transfer from DBR to DSR will remain pending. Once the software makes this bit as “1” and DSR_RDY also goes as “1” the transfer to DSR takes place. However, note that when this bit is 0, and the DSR_RDY becomes 1, still the transfer to the DSR will NOT happen. Only when this bit is a 1, will the transfer happen. This bit can be written in CONFIG and the Normal modes.

Table 1162. DOBCCR bit configurations and the related output states

Output path states	GTM_TRIG_SEL	SP_PULSE_SEL	OP_SEL
State1 ⁽¹⁾	0	1	1
State2 ⁽¹⁾	0	0	1
State3 ⁽¹⁾	1	1	1
State4 ⁽¹⁾	1	0	1
State5 ⁽¹⁾	1	x	0

1. These states are shown in [Section 53.8.2, Valid states for integrated sync pulse generator](#). In State5 the pulse width and period is to be controlled directly from the GTM. In this state, the PW0/1D registers have no effect on the Pulse Width Modulation, when observed on the “sdout” pin.

Note: Please refer to [Figure 1190](#) for the details about the above bits.

53.3.2.31 Manchester Decoder Disable Offset Register (PSI5_MDDIS_OFF)

The Manchester decoder Disable Offset register (PSI5_MDDIS_OFF) defines the time in intervals of 1 μ s, for which the Manchester decoder remains disabled after the falling edge of the sync pulse. Using this register, this time can be programmed from 0 μ s to 128 μ s. This works on the 1 μ s clock from the CGM.

Figure 1157. Manchester Decoder Disable Offset Register (PSI5_MDDIS_OFF)

Address: Base + 0x01A2 + (0x1C0 × channel)

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	MDDIS_OFF						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1163. PSI5_MDDIS_OFF field descriptions

Field	Description
0–15 MDDIS_OFF	These 7 bits can be used to program the time for which the Manchester decoder remains disabled. This offset is added AFTER the falling edge of the sync pulse. Thus the total time for which the Manchester decoder remains disabled = Tsynch + MDDIS_OFF where Tsynch is the high time for the sync pulse. Thus Tsynch = Pulse_Width0 or Pulse_Width1 as the case maybe, depending on whether a “0” is being pulse modulated or a “1”. Note that the Manchester decoder will ALWAYS remain disabled during the high time of the Sync Pulse. Using this register it is possible to disable the Manchester decoder BEYOND the Sync Pulse High Time as well. Figure 1195 shows the “MDDIS_OFF” definition.

53.3.2.32 Pulse Width for Data Bit 0 Register (PSI5_PW0D)[Figure 1158](#) shows the Pulse Width for Data Bit 0 Register.**Figure 1158. PSI5_Pulse Width for Data Bit 0 Register (PW0D)**

Address: Base + 0x01A4 + (0x1C0 × channel)

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	Pulse_Width0[6:0]						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1164. PSI5_PW0D field descriptions

Field	Description
0–15 Pulse_Width0	This defines the width (in μs) of data value '0' to be send from Data Output Register. It is the number of clock cycles(1μs clock) counted up to width “Pulse_Width0”; starting as soon as trigger appears from the ISPG (Internal Sync Pulse Generator) or the GTM. Can take max value of 127. When, intending to use the” tooth gap method” of PSI5 command transmission, the Pulse_Width0 should be configured to 0. Figure 1195 shows the definition of “Pulse_Width0”.

53.3.2.33 Pulse Width for Data Bit 1 Register (PSI5_PW1D)

Figure 1159 shows the Pulse Width for Data Bit 1 Register.

Figure 1159. PSI5_Pulse Width for Data Bit 1 Register (PW1D)

Address	Base + 0x01A6 + (0x1C0 × channel)															Access: User read/write
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	Pulse_Width1[6:0]						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1165. PSI5_PW1D field descriptions

Field	Description
0–15 Pulse_Width1	This defines the width (in μ s) of data value '1' to be send from Data Output Register. It is the number of clock cycles(1 μ s clock) counted up to width “Pulse_Width1”; starting as soon as trigger appears from the ISPG(Internal Sync Pulse Generator) or the GTM. Can take max value of 127. Figure 1195 shows the definition of “Pulse_Width1”.

Note: When using the “tooth gap method” of PSI5 command transmission, the pulse width is NOT disabled. In this case, PSI5_PW0D has to be programmed as 0. PSI5_PW1D has to have the value of the length of the pulse desired when a 1 has to be transferred.

53.3.2.34 Counter Target Pulse Register (PSI5_CTPR)

Figure 1160 shows the Counter Target Pulse Register.

Figure 1160. Counter Target Pulse Register (PSI5_CTPR)

Address:	Base + 0x01A8 + (0x1C0 × channel)															Access: User read/write

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1166. PSI5_CTPR field descriptions

Field	Description
0–15 CTPR	Counter Target Pulse Register. This is the target counter value. Once the CTC (channel target counter) reaches the value of CTPR this CTC is reset. CTC is a 16-bit free running counter that starts/stops depending on the CTC_GED (in GCR) bit or the CTC_ED bit (in PCCR). It gets reset initially when its value reaches CIPR and subsequently when its value reaches CTPR. The fact that which out of CTC_GED or the CTC_ED bit enables/disables it, is dependent on the CTC_GED_SEL bit in the PCCR. When CTC_GED/CTC_ED == 0 then the CTC is reset. The minimum value of CTPR is 6. Values less than 6 will be defaulted to 0 and the CTPR counter will not start. The value in CTPR indicates the time period of the internally generated sync pulses. The unmodulated (No PWM) internally generated sync pulses have a high time of 4-sp_ts_clk cycles, i.e., the duty cycle of the unmodulated internally generated sync pulses is $(4/ CTPR * 100)$. The 4 sp_ts_clk cycles is just the nascent value of the pulse that, actually triggers the PWD counters Note that this gives one more possible state, in addition to the states shown in Section 53.8.2, Valid states for integrated sync pulse generator. This additional state allows the output of the internal sync pulse generator to be made directly available at the output, without being pulse modulated. The CTPR describes ONLY the SYNC pulse period and not the sync pulse length, which is governed by the PWD registers, except in State5 where in the GTM governs these parameters.

Note: Please see [Section 53.8.1, Internal SYNC Pulse generation and coordination across PSI5 channels](#) for details about the Sync Pulse generation and coordination.

53.3.2.35 Counter Initialize Pulse Register (PSI5_CIPR)

[Figure 1161](#) shows the Counter Initialize Pulse Register.

Figure 1161. Counter Initialize Pulse Register (PSI5_CIPR)

Address: Base + 0x01AA + (0x1C0 × channel)

Access: User read/write

Table 1167. PSI5_CIPR field descriptions

Field	Description
0–15 CIPR[15:0]	Counter initialize pulse register. This is the value at which the CTC gets reset the first time, after which it is enabled using CTC_GED (in GCR) or the CTC_ED bit (in PCCR). All subsequent resets are done when the CTC value reaches CTPR. The CIPR is used to set the offset time between the start of sync pulses between two different PSI5 channels, when the CTC of both of these channels are started simultaneously using CTC_GED. The offset between any two PSI5 channels would be $CIPR_channel1 - CIPR_channel2$ sp_ts_clk cycles. Thus if channel 1 has a CIPR = 0 while channel2 has CIPR = 10, then the offset would be 10 sp_ts_clk cycles.

Note: The CIPR resolution is in terms of the time period of the “ sp_ts_clk ” ($T_{sp_ts_clk}$). Therefore the total “CIPR” time is “ $CIPR * T_{sp_ts_clk}$ ”, beginning from when the CIPR counters are enabled using the sync pulse trigger bits (PSI5_PCCR[CTC_ED] or PSI5_GCR[CTC_GED]). Due to internal Flop synchronization, this time would not exactly be $CIPR * T_{sp_ts_clk}$ but would have an inaccuracy of $1T_{sp_ts_clk}$. A further factor of $T_{ipg_clk_psi5}$ is also added to this inaccuracy.

The CTPR resolution is also in terms of the “ sp_ts_clk ”. Therefore the total “CTPR” time is “ $CTPR * T_{sp_ts_clk}$ ”. However when measured on the “sdout” pin of the IP this time would not exactly be “ $CTPR * T_{sp_ts_clk}$ ”. Due to internal Flop synchronization on the 1Mhz clock, an inaccuracy of “ $1\mu s$ ” would be added. A further factor of $T_{ipg_clk_psi5}$ is also added to this inaccuracy. Hence the “CTPR” period measured on the “sdout” pin, can range from $(CTPR * T_{sp_ts_clk}) - 1\mu s - T_{ipg_clk_psi5}$ to $(CTPR * T_{sp_ts_clk}) + 1\mu s + T_{ipg_clk_psi5}$. Please see [Figure 1195](#) for more details about this inaccuracy.

Please see [Section 53.8.1, Internal SYNC Pulse generation and coordination across PSI5 channels](#) for details about the Sync Pulse generation and coordination.

53.3.2.36 Data Preparation Register Low (PSI5_DPRL)

[Figure 1162](#) shows the Data Preparation Register Low.

Table 1168. DPRL PSI5_field descriptions

Field	Description																		
8–31 DPR[23:0]	DPR[23:0] are the 24-bits of the DPR register used for writing the variable length, standard ECU-to-Sensor commands, comprising of the address, data and other fields. Note that the IP is transparent to the arrangement of the address, data and other fields and it treats the bits in these fields identically for the purpose of CRC calculation and transmission. This register is writable only when using the standard length PSI5 frames. For details about CRC calculation please refer to Section 53.4.3.4, Data transmission. The writable bits in this register are governed by the PSI5_DBOCR[CMD_TYPE] bit fields as per the following description: <table><tr><th>PSI5_DBOCR[CMD_TYPE]</th><th>Standard PSI5 FRAME Types</th><th>Writeable bits in PSI5_DPRL</th></tr><tr><td>“0” or “1”</td><td>Short Frame</td><td>6(DPR[5:0])</td></tr><tr><td>“2” or “3”</td><td>Long Frame</td><td>16(DPR[15:0])</td></tr><tr><td>“4” or “5”</td><td>X-Long Frame</td><td>22(DPR[21:0])</td></tr><tr><td>“6”</td><td>XX-Long Frame</td><td>24(DPR[23:0])</td></tr><tr><td>“7”</td><td>Not Available for write</td><td>Not Available for write</td></tr></table> Note that the unwriteable bits in this register field are always read as “0s”. This register has to be written by the CPU. These bits can be written only in the Normal mode.	PSI5_DBOCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writeable bits in PSI5_DPRL	“0” or “1”	Short Frame	6(DPR[5:0])	“2” or “3”	Long Frame	16(DPR[15:0])	“4” or “5”	X-Long Frame	22(DPR[21:0])	“6”	XX-Long Frame	24(DPR[23:0])	“7”	Not Available for write	Not Available for write
PSI5_DBOCR[CMD_TYPE]	Standard PSI5 FRAME Types	Writeable bits in PSI5_DPRL																	
“0” or “1”	Short Frame	6(DPR[5:0])																	
“2” or “3”	Long Frame	16(DPR[15:0])																	
“4” or “5”	X-Long Frame	22(DPR[21:0])																	
“6”	XX-Long Frame	24(DPR[23:0])																	
“7”	Not Available for write	Not Available for write																	

Note: This register is the lower register used for writing the standard data and the address commands and is to be used for writing standard length ECU-to-sensor commands. The CRC/stuff/start bits are automatically appended by the hardware before the command is transferred to DBR. The commands to this register are accepted ONLY when $PSI5_GISR[DPR_RDY] == 1$. Whenever $PSI5_GISR[DPR_RDY] == 1$, then each bit of this register defaults to 0. Writing to this register when $PSI5_GISR[DPR_RDY] == 0$ will cause the $PSI5_GISR[IS_PROW]$ status bit to be set and the generation of an error interrupt, if it is enabled. Further, trying to write to this register when $PSI5_DOBCR[CMD_TYPE] = “7”$ results in the setting of the $PSI5_GISR[IS_PROW]$ bit and the resulting write is rejected.

53.3.2.37 Data Preparation Register High (PSI5_DPRH)

		DBR[7]	1'b1(stuff)
		DBR[6:4]	DPR[2:0]
		DBR[3]	1'b1(stuff)
		DBR[2:0]	“010”(start seq)

This register is writable only in Normal mode.

Note: When `DEFAULT_SYNC == 0` then default value of this register is `00000000`. When `DEFAULT_SYNC == 1` then the default value of this register is `FFFFFFF`. Note that the default value is different from the reset value. The reset value of this register is always “00000000”. The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when `PSI5_GISR[DBR_RDY] == 1`. Whenever `PSI5_GISR[DBR_RDY] == 1` then each bit of this register defaults to `DEFAULT_SYNC` value. Writing to this register when `PSI5_GISR[DBR_RDY] == 0` will set the status bit `PSI5_GISR[IS_BROW]` and generate an error interrupt, if it is enabled.

53.3.2.39 Data Buffer Register High (PSI5_DBRH)

Table 1171. PSI5_DBRH field descriptions

Field	Description																																				
0—31 DBR[63:32]	This register contains the Upper 32 bits(DBR[63:32]) of the max-64 bit length command (DBR[63:0]). The lower bits, DBR[31:0] are contained in the DBRL register. These fields can automatically be updated by the hardware (when the CRC/stuff/start bits are appended to the data in DPRL) or these fields can be written by the CPU (when PSI5_GISR[DBR_RDY] == 1 in the Normal mode).Hardware update occurs when PSI5_GISR[DPR_RDY]== 0and PSI5_GISR[DBR_RDY] == 1. Depending on the PSI5_DOBCR[CMD_TYPE] value this register can have different data assignments as describe in the below tables. Note that when PSI5_DOBCR[CMD_TYPE] == “7”), then only the CPU can write to these registers. <table><tr><th>PSI5_DOBCR [CMD_TYPE]</th><th>DBR bits</th><th>Bit Assignment</th></tr><tr><td>“7” - Non Standard Frame lengths</td><td>DBR[63:32]]</td><td>Variable length of writeable bits, as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]</td></tr></table> <table><tr><th>PSI5_DOBCR [CMD_TYPE]</th><th>DBR bits</th><th>Bit Assignment</th></tr><tr><td rowspan="4">“6” - XX Long</td><td>DBR[63:43]</td><td>All 0s</td></tr><tr><td>DBR[42:37]</td><td>{CRC[5],CRC[4],CRC[3],CRC[2],CRC[1],CRC[0]}</td></tr><tr><td>DBR[36]</td><td>1'b0(stuff)</td></tr><tr><td>DBR[32:35]</td><td>DPR[23:20]</td></tr></table> <table><tr><th>PSI5_DOBCR [CMD_TYPE]</th><th>DBR bits</th><th>Bit Assignment</th></tr><tr><td rowspan="4">“4” or “5” -X Long</td><td>DBR[63:37]</td><td>All 0s</td></tr><tr><td>DBR[36]</td><td>CRC[0]</td></tr><tr><td>DBR[35]</td><td>1'b1((stuff)</td></tr><tr><td>DBR[34:32]</td><td>{CRC[1],CRC[2],DPR[21]}</td></tr></table> <table><tr><th>PSI5_DOBCR [CMD_TYPE]</th><th>DBR bits</th><th>Bit Assignment</th></tr><tr><td>“3” or “2”(Long) OR “1” or “0”(Short)</td><td>DBR[63:32]</td><td>All 0s</td></tr></table>	PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment	“7” - Non Standard Frame lengths	DBR[63:32]]	Variable length of writeable bits, as per the length programmed in the PSI5_DOBCR[DATA_LENGTH]	PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment	“6” - XX Long	DBR[63:43]	All 0s	DBR[42:37]	{CRC[5],CRC[4],CRC[3],CRC[2],CRC[1],CRC[0]}	DBR[36]	1'b0(stuff)	DBR[32:35]	DPR[23:20]	PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment	“4” or “5” -X Long	DBR[63:37]	All 0s	DBR[36]	CRC[0]	DBR[35]	1'b1((stuff)	DBR[34:32]	{CRC[1],CRC[2],DPR[21]}	PSI5_DOBCR [CMD_TYPE]	DBR bits	Bit Assignment	“3” or “2”(Long) OR “1” or “0”(Short)	DBR[63:32]	All 0s

“3” or “2”(Long) OR “1” or “0”(Short)	DBR[63:32]	All 0s																																			

This register is CPU writable only in Normal mode.

Note: When `DEFAULT_SYNC == 0` then the default value of this register is `00000000`. When `DEFAULT_SYNC == 1` then the default value of this register is `FFFFFFF`. Note that the default value is different from the reset value. The reset value of this register is always `"00000000"`. The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when `PSI5_GISR[DBR_RDY] == 1`. Whenever `PSI5_GISR[DBR_RDY] == 1` then each bit of this register defaults to `DEFAULT_SYNC` value. Writing to this register when `PSI5_GISR[DBR_RDY] == 0` will set the status bit `PSI5_GISR[IS_BROW]` and generate an error interrupt, if it is enabled.

53.3.2.40 Data Shift Register Low (PSI5_DSRL)

Table 1172. PSI5_DSRL field descriptions

Field	Description
0-31 DSR[31:0]	These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of <code>PSI5_DOBDR[CMD_TYPE[2:0]]</code> register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRL. Thus when updated by the hardware, then <code>DSR[31:0] = DBR[31:0]</code>. Hardware update occurs when <code>PSI5_GISR[DSR_RDY] == 1</code> and <code>PSI5_GISR[DBR_RDY] == 0</code> and <code>PSI5_DOBDR[SW_READY] == 1</code>. Note that if <code>PSI5_DOBDR[SW_READY] == 0</code> then the update of the data from the DBR to DSR will NOT happen even though <code>PSI5_GISR[DSR_RDY] == 1</code>. These bits can be written by the CPU in the Normal mode, when <code>PSI5_GISR[DSR_RDY] == 1</code>.

This register is CPU writable only in Normal mode.

Note: When `DEFAULT_SYNC == 0` then default value of this register is `00000000`. When `DEFAULT_SYNC == 1` then the default value of this register is `FFFFFFF`. Note that the default value is different from the reset value. The reset value of this register is always “00000000”. The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when `PSI5_GISR[DSR_RDY] == 1`. Whenever `PSI5_GISR[DBR_RDY] == 1` then each bit of this register defaults to `DEFAULT_SYNC` value. Writing to this register when `PSI5_GISR[DSR_RDY] == 0` will set the status bit `GISR[IS_DSROW]` and generate an error interrupt, if it is enabled. Note that for the hardware update of DSR with DBR contents, additional condition `PSI5_DOBCR[SW_READY] == 1`, should also be satisfied in addition to `PSI5_GISR[DSR_RDY] == 1`.

53.3.2.41 Data Shift Register High (PSI5_DSRH)

Figure 1167 shows the Data Shift Register High.

Table 1173. PSI5_DSRH field descriptions

Field	Description
0-31 DSR[63:32]	These bits can be updated by the hardware or can be written by the CPU. The number of accessible bits in DSR are always equal to the number of accessible bits in DBR, which in turn depend on the value of <code>PSI5_DOBCR[CMD_TYPE[2:0]]</code> register bits. When these bits are updated by the hardware then there is a one to one correspondence between the bit positions in this register and the bit positions in the DBRH. Thus when updated by the hardware, then <code>DSR[63:32] = DBR[63:32]</code>. Hardware update occurs when <code>PSI5_GISR[DSR_RDY] == 1</code> and <code>PSI5_GISR[DBR_RDY] == 0</code> and <code>PSI5_DOBCR[SW_READY] == 1</code>. Note that if <code>PSI5_DOBCR[SW_READY] == 0</code> then the update of the data from the DBR to DSR will NOT happen even though <code>PSI5_GISR[DSR_RDY] == 1</code>. These bits can be written by the CPU in the Normal mode, when <code>PSI5_GISR[DSR_RDY] == 1'b1</code>.

This register is writable only in Normal mode.

Note: When `DEFAULT_SYNC == 0` then the default value of this register is `00000000`. When `DEFAULT_SYNC == 1` then the default value of this register is `FFFFFFFF`. Note that the default value is different from the reset value. The reset value of this register is always “00000000”. The default value is loaded once the IP enters the NORMAL mode.

Further, the commands to this register are accepted ONLY when `PSI5_GISR[DSR_RDY] == 1`. Whenever `PSI5_GISR[DBR_RDY] == 1` then each bit of this register defaults to `DEFAULT_SYNC` value. Writing to this register when `PSI5_GISR[DSR_RDY] == 0` will set the status bit `GISR[IS_DSROW]` and generate an error interrupt, if it is enabled. Note that for the hardware update of DSR with DBR contents, additional condition `PSI5_DOBCR[SW_READY] == 1`, should also be satisfied in addition to `PSI5_GISR[DSR_RDY] == 1`.

53.3.2.42 Device modes and Register bit accesses

1. The following bits are writable in all modes (Normal, Config, and Disable).
 - `GCR[GLOBAL_DISABLE_REQ]`
 - `PCCR[PSI5_CH_CONFIG]`
 - `PCCR[PSI5_CH_EN]`
 - Global Counter Enable/Disable (`GCR[CTC_GED]`). This is to allow the Sync Pulse Generator to be enabled/disabled independently among those channels that are used for staggering, irrespective of the state of the channels NOT being used for staggering.
2. The following register is writable only in Normal mode and is initialized to all 0s.
 - `DPRL`
3. The following registers are writable ONLY in Normal mode. Initial is at ion in Config mode depends on the value of `PSI5_DOBCR[DEFAULT_SYNC]` bit. When `PSI5_DOBCR[DEFAULT_SYNC] == 1` in Config mode, then the below registers are initialized to all 1s in Normal mode. When `PSI5_DOBCR[DEFAULT_SYNC] = 0` in Config mode, then the below registers are initialized to all 0s in Normal mode. Once in Normal mode, these registers can then be programmed for any command that needs to be sent.
 - `DBRH/DBRL`
 - `DSRH/DSRL`
4. The following registers are writable in Config and Normal modes only:
 - All interrupt control registers
 - All SET registers (the one shot registers that are used to set the error flags for software drivers)
 - Channel Enable/Disable (`PCCR[CTC_ED]`). Using this it is possible to allow the Sync Pulse Generator to be enabled/disabled in Normal mode. The counter is reset when `CTC_ED == 0`
 - All w1c bits
5. Apart from these, all other register bits can be written only in Config mode, including the Data registers (`PMRH/PMRL/SFRn`), that, in Normal mode, are updated by the hardware only.
6. Debug mode: If the device is in Normal mode and the debug mode is enabled, then ONLY the registers in [Section 53.3.2.42, Device modes and Register bit accesses](#):^{(1),(2),(3),(4)} can be written by the debugger. ⁽⁵⁾ of [Section 53.3.2.42, Device modes and Register bit accesses](#) will not be available for write through the debugger.

In case the debugger has to change any register, then the device has to be brought in the Disable → Config mode. The debugger can, however, read any register in any mode.

53.4 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. [Figure 1168](#) shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 1168. System setup (peripheral sensor connected to device)

ECU (Electronic Control Unit) is comprised of PSI5 digital interface and the PSI5 transceiver (present externally).

53.4.1 Sensor-to-ECU communication

53.4.1.1 Physical layer

The PSI5 uses two wires to provide both power supply and data transmission to the sensors. The ECU provides a pre-regulated voltage to the sensors. Data transmission from the sensor to the ECU is done by current modulation on the power supply lines. Current oscillations are damped by the ECU.

53.4.1.2 Bit encoding

A “low” level ($I_{S,Low}$) is represented by the Normal (quiescent) current consumption of the sensor(s). A “high” level ($I_{S,High}$) is generated by an increased current sink of the sensor ($I_{S,Low} + \dots I_S$). The current modulation is detected within the PSI5 transceiver.

Manchester coding is used for data transmission. A logic 0 is represented by a rising slope and a logic 1 by a falling slope of the current in the middle of T bit.

Figure 1169. Bit encoding of data from sensor

53.4.1.3 Synchronization

For synchronized operation and bus mode, a sync pulse is generated by the PSI5 receiver. The sync pulse is output from the integrated PSI5 receiver to an external PSI5 transceiver that processes these pulses to a pre-regulated voltage level on supply lines to sensors. The voltage change is detected within the sensors.

53.4.2 Data Link Layer

Data bit decoding

The PSI5 message is received as serial Manchester-coded bits. The bit stream is passed through a Manchester decoder stage that converts it to normal NRZ format bit by bit and stores it serially in the receive register (64 bits). This block clearly identifies start (00) and end of receive frame using preprogrammed frame configuration registers.

- The Manchester-coded bits can be received at the rate of 125 Kbit/s or 189 Kbit/s (selectable by programming frame configuration registers).
- The Manchester decoder is designed to consider data with duty cycle of 30–70%.
- The bit decoding is done using an oversampling and counting algorithm with majority voting and edge recognition. $(125/189 \text{ kHz}) \times 32$, i.e., (4/6.048 MHz also referred as 32× clock) clocks are supplied from a common clock generator (to be implemented in CGM) module. This clock is used for oversampling of the receive bit and thereby decoding it as normal 1 or 0 (NRZ).
- The Manchester decoder is masked (switched off) for the duration when the sync pulse is transmitted. In addition to this, it can be configured to be off for an additional time, after the falling edge of the sync pulse. The duration of this time is configurable in the MDDIS_OFF register. It uses a 2003 voter to recognize the encoded half bits.
- There is a 3005 majority voting glitch filter at the data input of the Manchester decoder.

53.4.2.1 Reception of data frames

The extended PSI5 (Power Train Applications) receive data frame consists of p bits containing:

- Two start bits (S1 and S2) {S1=0, S2=0}
- One parity bit (P) with even parity (or 3 CRC bits C0, C1, and C2).
- A data region (D0.....D[$k - 1$]) with $k = 8$ to 28 bits with 1-bit granularity.
- The total length of a PSI5 frame is $p = k + 3$ data bits (in case of frames with parity bit) or $p = k + 5$ data bits (in case of frames with CRC).
- Data bits are received LSB first. The parity or CRC check bits cover the bits of the entire data region.

The length of the data region can vary between $k = 8$ to 28 bits (with 1-bit granularity). The data region can be split into the following fields and regions:

- The bits D0 and D1 can optionally represent Serial Messaging Channel M0, M1.
 - This Serial Messaging Channel (SMC) is used to receive initialization data during fast startup phase or slow acknowledgement/response messages (to command transmitted from ECU requesting data or diagnostic information from the sensor).

Note, that the maximum length of the entire data region is 28 bits. Thus the signal payload region and the optional data fields cannot concurrently be used at their maximum length in some cases.

As the PSI5 module is targeted for powertrain applications, the data frame format differs from standard PSI5 frames for safety applications specified in version 1.3 of the PSI5 specifications. More specifically for supporting the version 2.0 powertrain substandard. The Powertrain data frame format and optional Serial Messaging Channel (SMC) frame format are shown in [Figure 1170](#).

Figure 1170. Receive data frame format

A) PSI5 Receive Data Frame Format (Power Train Applications)

B) SMC Data Frame Format

Note: SMC frame encoded along with regular PSI5 data frames

53.4.2.2 Data Frame Configuration Control

Figure 1171. Data frame configuration and sampling

At the receive path, as many as six frame slots (reception windows) can be programmed with a start time of consecutive slots (slot1 to slot6) and end time or last slot, which can be configured through the Slot *n* Start/End Configuration Registers ([Section 53.3.2.28, Slot *n* Start Boundary Register \(PSI5_SnSBR\)](#) and [Section 53.3.2.29, Slot *n* End Boundary Register \(PSI5_SnEBR\)](#)) there are seven registers for six slots. The slot time value is with respect to timing sync pulse.

The following range is always maintained for T_{sync} (during programming of the GCR and CTPR registers) when timing (sync) pulses are generated through the Sync Pulse Generator.

Equation 80 $T_{\text{sync}} < 16 \text{ ms}$

For the maximum defined six frame slots, six frame configuration registers (S1FCR, S2FCR, S3FCR, S4FCR, S5FCR, and S6FCR) are also available. In these registers it is possible to configure the payload region of the expected frames, in addition to other channel-specific parameters.

53.4.2.3 Data frame handling

[Figure 1172](#) shows the detection of the start bits and the various parameters for the same.

Figure 1172. Start Bit Detection

1. If DND is set to '1' because a message has overlapped with the Manchester decoder disable phase, then the Manchester decoder disable phase will be extended till the end of the first configured slot. DND will be cleared to '0' at the end of this first slot and NO_DETECT_STATE will be entered immediately. No idle detect will be carried out (i.e. PSI5_clk32x_idle_detect_cnt will not be started) to ensure that a message occurring within the first bit time of slot2 will be captured.
2. If DND is set to '1' because a first message (MSGn) has overlapped with a second message (MSGn+1), then MSGn+1 will be ignored i.e. the Manchester decoder will be disabled until the end of the slot in which MSGn+1 was expected. This will be the case whether the first transition detect of MSGn+1 occurs in the expected slot of MSGn or MSGn+1. At the end of the slot in which MSGn+1 was expected, DND will be cleared to '0' and NO_DETECT_STATE will be entered immediately. No idle detect will be carried out (i.e. PSI5_clk32x_idle_detect_cnt will not be started) to ensure that a message occurring within the first bit time of the slot in which the next message (MSGn+2) is expected will be captured.

Figure 1173 shows how the bits are differentiated into a “1” or a “0” based on the various margins and sample points.

Figure 1173. Bit Extraction

Start Sequence Measured: $T_p = 32$ and $TDCH = 20$

Calculations:

$TDCL = T_p - TDCH = 12$; $\Delta DC = TDCH - T_p/2 = 4$; $TMarginL = TDCL/2 = 6$; $TMarginH = TDCH/2 = 10$

If $DATA_BIT(N) = 0$, $TWL = TDCH + TMarginL = 26$; signal sampled at $TWL - 3$, -2 and -1

• if signal low, expect rising edge between $TWL0$ and $TWR0$ then $DATA_BIT(N+1) = 0$. $TWL0 = TDCH + TMarginL$, $TWR0 = T_p + TMarginH$.

• if signal high, expect falling edge between $TWL0$ and $TWR0$ then $DATA_BIT(N+1) = 1$. $TWL0 = TDCH + TMarginL$, $TWR0 = T_p + \Delta DC + TMarginL$.

If $DATA_BIT(N) = 1$, $TWL = TDCL + TMarginH = 22$; signal sampled at $TWL - 3$, -2 and -1

• if signal low, expect rising edge between $TWL1$ and $TWR1$ then $DATA_BIT(N+1) = 0$. $TWL1 = TDCL + TMarginH$, $TWR1 = T_p - \Delta DC + TMarginH$.

• if signal high, expect falling edge between $TWL1$ and $TWR1$ then $DATA_BIT(N+1) = 1$. $TWL1 = TDCL + TMarginH$, $TWR1 = T_p + TMarginL$.

PSI5_edge_cnt will be stopped (PSI5_data_start low) at $TDCH$ if $CRC0$ is logic 0 or $TDCL$ if $CRC0$ is logic 1.

53.4.2.3.1 Start of frame recognition

The start of frame recognition is as follows:

- With the Manchester decoder in NO_DETECT state, the first rising edge of the incoming data signal is captured and assumed to be the midpoint transition of the first start bit $S0$.
- As soon as the first rising edge ($S0$) on the bus is recognized, the 24-bit time stamp value is captured internally. On the rising edge of the $S1$ this value is stored in the data

receive register and available for processing. If a valid S1 edge is NOT recognized then this time stamp value is discarded and not stored in any register.

- The middle transition from the first start bit S0 to the second start bit S1 is assumed to be the bit duration for the rest of the bits.
- The time of the high period is measured using the 32* sample clock to enable analysis of the data signal duty cycle. The measured value is used in the data state to calculate the appropriate sample time of the first half-bit of the following data bits
- The second rising edge of the incoming data (S1) is captured and assumed to be the mid-point transition from the second start bit S1 if it appears in the allowed range of samples of the 32x sample clock.
- The time between the first and second rising edge is measured using the 32x sample clock to enable analysis of the sensor clock tolerance. The measured value is used together with the calculated duty cycle to set the window for capturing the mid-point bit transition the following data bits.
- [Figure 1172](#) and [Figure 1173](#) show the start bit and the data bit extraction mechanisms respectively, in the Manchester decoder.

53.4.2.3.2 Data state

In the data state, the Manchester decoder samples the number of data bits corresponding to the configured length of the data payload region and 3-bit CRC or 1-bit parity.

53.4.2.3.3 Message diagnostic checks

During the data state, electrical correctness of each bit in regard of Manchester encoding is checked. If an incorrect bit is detected, a 0 is written into the data payload region. Following completion of reception, correctness of the entire message is checked with the CRC and timing of the message reception.

- CRC is recalculated for the data and compared with received CRC bits. The CRC comparison result is stored as a status bit, denoted as the C field in the receive register and the RAM register. Irrespective of the value of the "C" bit the, the frame is always stored in the RAM register and is never discarded.
- If at least one bit is electrically faulty (apart from M0M1), then the bit field E is set to 1 and stored as status bit in the receive register and the RAM register.
- The EM bit is set to 1 if any of M0 or M1 bits are electrically faulty. Note that the E and the EM bits can be set only when a valid start sequence has been detected.
- Set status bit field T in the receive register to 1 if the frame received is in the wrong slot (boundary violations). This bit is NOT set for asynchronous modes.
- Set status bit F if no frame is received in defined frame slot. This bit is NOT set for asynchronous modes.

53.4.2.3.4 The incoming frames after the sync pulse are to be numbered from 1 to 6 (max). This is done by a 3-bit slot counter, which is incremented automatically after the end of each slot irrespective of whether a valid message is received or not. This 3-bit value is stored in the receive register and the RAM registers as the "slot_counter" field. **T-bit Handling**

The following paragraphs describe how the IP handles error cases that generate T bit errors. A number of examples are shown, including the error free case, which is used to explain the reception process.

53.4.2.3.4.1 Error Free Case

Figure 1174. Error Free Case

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this case, all messages are received in the correct slots.

- As soon as the Manchester decoder block is enabled (after the SYNC pulse has finished and any configured disable offset has expired, pink region) the IP checks for the first configured message and starts monitoring the output of the PSI5 transceiver.
- The IP identifies a correct start of message sequence ($S0, S1 == '00'$), and captures the slot counter when the first rising edge of the start sequence is detected. This first rising edge detected is the mid-point transition of the Manchester encoded S0 bit of the message start sequence
- The expected number of bits configured in the message is received and decoded. Any error in the Manchester encoded bits of the message E bit is set - unless the error is in one of the first two bits and SMC message is configured, in which case the EM bit is set.
- After the final bit is received, a check is made that the message CRC or parity is correct. If the CRC or parity check is not correct, C bit is set for the message.
- Once the CRC checks have been made, the received message — along with the status bits, slot counter in which the start sequence was received, the timestamp of the message, the message data and CRC or parity is saved to the channel message FIFO.
- As soon as the received message has been stored, the idle state of the bus is verified and monitoring of the transceiver output restarts to check for the next configured message
- If the serial message channel (SMC) is configured, the first two data bits are extracted from a sequence of 7 PSI5 messages as long as no electrical error is detected in those bits (EM error). If the correct start sequence for the SMC message is detected on M1 (6 logical 1s and a logical 0) in those 7 messages, M0 and M1 from the following 11 messages are also extracted and saved in the SMC buffer allocated to the slot in which

the PSI5 message is received (in total, 18 PSI5 messages are needed to build one SMC message). When the SMC has been received, the CRC is checked and the status of the check is saved in the SMC buffer. If an EM error occurs after a start sequence has been detected and before the end of the message is reached, M0 and M1 are both saved as 0 and the rest of the message is received, at which point the CRC is checked as normal.

53.4.2.3.4.2 Message Too Early

Figure 1175. Message Too Early

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	1	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 reception starts early, before slot 2 boundary is crossed, and so the slot counter is captured as “1” and because the message starts in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG2 has been received but not entirely in it’s correct slot. The status of the message will include the T bit set and slot counter will be 1, so software can interpret that MSG2 was too early.

The SMC message is received correctly.

53.4.2.3.4.3 Message Too Late

Figure 1176. Message Too Late

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG1 reception starts later than expected and ends after slot 2 boundary is crossed. The slot counter is captured as “1” and because the message ends in the wrong slot, the T bit is set. If no other errors are detected during reception, the assumption is that the correct MSG1 has been received but not entirely in it’s correct slot. The status of the message will include the T bit set and slot counter will be “1”, so software can interpret that MSG1 was late.

The SMC message is received correctly.

53.4.2.3.4.4 Message Missing

Figure 1177. Message Missing

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	Yes	No	No	2	0/0
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 is missing.

At the end of slot 2, the IP writes message buffer location 2 (MSG2 location) with slot counter 2 and the F bit set. The data and timestamp regions are filled with 0s.

The IP waits until the start of the next configured slot (slot 4) to update the SMC buffer 2 with "00". If slot 4 was not configured, the SMC for the missing MSG2 would be updated at the end of the final slot.

53.4.2.3.4.5 Message Much Too Late (in unconfigured slot)

Figure 1178. Message Much Too Late (in unconfigured slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2a	2	No	Yes	No	No	2	No update
MSG2b	3	Yes	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG2 reception doesn't start in its own slot, and the F bit is set for message buffer location 2 (MSG2a).

Because slot 3 is unconfigured, the IP continues to wait for MSG2 in slot 3 and does not update the SMC message buffer 2. The IP recognizes the MSG2 start condition in the normal way and updates PSI5 message buffer 3 (MSG2b), capturing slot 3 as the start slot counter and setting T bit, so that the software can recognize that MSG2 has come in slot 3.

When MSG2 has been received, SMC message buffer 2 is updated at the end of slot 3. MSG4 is received normally.

Note: .Any scenario where an expected message arrives in an unconfigured slot, leads to an issue when DMA access is used to read the PSI5 message buffer. This is because instead of the expected three entries in the PSI5 message buffer, there will be four, and assuming the DMA watermark is set for the expected three messages, the DMA request will be activated before MSG4 has been received.

In order to overcome this, if DMA access is required, no slots can be left unconfigured and the DMA watermark must be set to the number of slots in the SYNC period. In that way, the DMA will always be synchronised, but depending on how the 'empty' slot is configured, when a message is too late as described here, the result can be that the late message and its associated SMC content is lost.

53.4.2.3.4.6 Message Much Too Late (in unconfigured slot)

Figure 1179. Message Much Too Late (in unconfigured slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1a	1	No	Yes	No	No	No	No
MSG1b	3	Yes	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG1 is received much too late, in the second of two unconfigured slots.

When MSG1 does not arrive in slot 1, MSG1a is saved in the message buffer with F bit set. The IP waits throughout the two unconfigured slots and is received in slot 3 with slot counter 3. Because MSG1b is received completely in slot 3 it is saved in the message buffer with T bit set.

MSG4 is received normally.

53.4.2.3.4.7 Message Too Late (in last slot)

Figure 1180. Message Too Late (in last slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	No	No	4	M0/M1

In this scenario, the last message is received late.

MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the end of the final slot, but before the Manchester decoder is disabled by the SYNC pulse on the bus. The message is received correctly with the T bit set.

53.4.2.3.4.8 Message Too Late (in last slot)

Figure 1181. Message Too Late (in last slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	No	No	No	No	No
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	Yes	No	Yes	Yes	4	M0/M1 or 0/0

In this scenario, the last message is received late in the last slot.

MSG1 and MSG2 are received error free.

MSG4 is late with the start sequence identified in the correct slot 4, with slot counter 4 captured. The end of the message occurs after the Manchester decoder is disabled by the SYNC pulse on the bus, so the last part of the message cannot be received correctly. Nevertheless, the message reception is completed and the message is stored in the message buffer with the T bit set and 0 written in the buffer for all bits received while the Manchester decoder is disabled. This leads to E and C bit errors.

In an extreme case, it could also lead to EM bit errors, in which case the SMC buffer will also be written with (0,0) otherwise, the correct bits are written to the SMC buffer.

53.4.2.3.4.9 Message Too Early (in first slot)

Figure 1182. Message Too Early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	0	Yes	No	No	No	1	M0/M1
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, the first message is received early.

As soon as the Manchester decoder disable phase has ended, the IP verifies the idle condition on the signal line and then looks for the first message start sequence. MSG1 start sequence is received before the start of slot 1 with slot counter 0 captured. MSG1 is then received normally and saved with slot counter 0 and T bit set.

SMC bits M0/M1 are saved to SMC buffer 1.

MSG2 and MSG4 are received normally.

Note: *.This scenario can be avoided if the start of slot 1 is configured to coincide with the end of the Manchester decoder disable phase.*

53.4.2.3.4.10 Message Too Early (in first slot and overlaps Manchester Decoder disable)

Figure 1183. Message Too Early (in first slot)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	No	Yes	No	No	1	0/0
MSG2	2	No	No	No	No	2	M0/M1
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, the first message is received early and overlaps with the Manchester decoder disable phase.

As soon as the Manchester decoder disable phase has ended, the IP starts looking for “idle condition” on the signal line by monitoring it for 42 counts of the sample clock. If the signal line is found to be initially high or if a valid transition occurs in the time frame of 42 samples of the sample clock, the Manchester decoder stops decoding until the end of slot 1. Decoding will restart at the beginning of slot 2.

MSG1 is assumed to be lost and the “F” bit is set for that message with the Slot Counter as “1”. If MSG1 SMC is configured then SMC is saved with “00” appended for the M0/M1 bits.

53.4.2.3.4.11 Message Too Late (overlaps next message)

Figure 1184. Message Too Late (overlaps next message)

Message Name	Slot Counter	T-bit	F-bit	E/EM-bit	C-bit	SMC buffer	SMC data
MSG1	1	Yes	No	Yes	Yes	1	M0/M1
MSG2	2	No	Yes	No	No	2	0/0
MSG3	3	No	No	No	No	No	No
MSG4	4	No	No	No	No	4	M0/M1

In this scenario, MSG1 is received too late and overlaps with MSG2.

MSG1 start is recognized in slot 1. The last bits of MSG1 are disrupted by the start of MSG2 leading to likely E and C bit errors.

At the end of MSG1, idle time is found to be violated by either the signal line being high as soon as NO_DETECT_STATE is entered or FIRST_TRANSITION_DETECT occurs within 42 counts of the idle detect sample clock. The Manchester decoder stops decoding until the end of slot 2. Decoding is restarted at the start of slot3. MSG2 is not received and MSG2 location in the memory will be saved with the F-bit set. The SMC buffer 2 will be updated with 00.

MSG3 and MSG4 are received correctly in their own slots.

53.4.2.3.5 Data Frame Storage

Once the data frame is received and all required status fields updated (for example, Time stamp, C, E, EM, T, F and Frame Counter), this 64-bit value in the data receive register is moved to the RAM Register (PMB).

- This RAM buffer is a 32 (depth) × 64 (frame size) register array with DMA transfer capability (both single or burst).
- Also, the individual RAM locations can be accessed directly by the microcontroller core any time.
- Care needs to be taken that receive data is assigned to the sensor and frame slot unambiguously.

53.4.2.3.6 Message diagnostics

Apart from the regular status bits (mentioned above), a few more diagnostic checks are done and stored as status bits along with each data frame location in RAM. These are:

- Diagnosis registers are associated with each sensor data RAM buffer to indicate
 - RAM buffer has been filled with data.
 - RAM buffer has been overwritten before data previously stored was read.
 - Data written to buffer includes an error bit (E, EM, C, T, or F, configurable).
- The diagnosis registers are able to be read with a single DMA access.
- After successfully completing a read access, these registers are reset by hardware. This is done by mapping these diagnosis bits byte-wise so that one byte access clears a single bit without affecting other bits.

Figure 1185. Diagnosis Information attached to every frame

Note: See [Section 53.8.3, Implementation of EI Diagnostic Register](#) for more detail.

53.4.2.3.7 SMC message extraction

The optional messaging channel M0, M1 (shown in [Figure 1170](#)) is used by sensors to send an SMC frame along with the normal PSI5 frame. It takes 18 PSI5 frames to send one SMC frame.

The extraction of SMC bits is done for each slot separately and stored separately into the SMC frame receive buffers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (width of SMC frame, as defined below)

The extraction logic works as follows:

- Search for SMC start sequence 111111 followed by 0 on M1 and keep storing last 6 bits {CRC} on M0.
- If the start sequence is detected it continues with further extraction and storage of M1 and M0.
 - Store the extracted frame on the corresponding slot buffer.
 - Move the SMC frame to corresponding SFR[i] register period. Once complete, the SMC frame is extracted and generates an interrupt, so that it can be read by the CPU.
 - If the start sequence is not detected, it continues with the search.

The SMC frame is extracted in hardware and stored separately as memory-mapped registers. The size of the SMC frame receive buffers is 6 (no of slots) × 32 (width of SMC frame).

53.4.2.4 Message Read Logic

PSI5 supports two kinds of read access to received sensor data.

- Read access through memory-mapped RAM registers. These registers can be read by the CPU any time or, specifically, when the concerned interrupts are raised. Applicable for both the SMC and the PSI5 messages.
- Read access through DMA request. Here the DMA sequencer treats the memory-mapped registers as a block and reads them sequentially. Note that even if the DMA is used, the CPU can read the RAM registers any time by addressing them. This is applicable for both the SMC and the PSI5 messages. When reading the PSI5 messages, it is possible to read only the PSI5 messages or PSI5 + diagnostic registers.

Figure 1186. PSI5 and SMC Message Read Logic Block

53.4.2.5 CRC Recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 1187. CRC calculation scheme

Table 1174. CRC Calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 1175. Transmitted and Received Sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1176. CRC Re-Calculation (At Receiver Side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

53.4.3 ECU-to-sensor communication

Whereas the sensor-to-ECU communication is realized by current modulation, voltage modulation on the supply lines is used to transmit commands to the sensors. A predefined start sequence allows the sensors to recognize that a command is being transmitted during all synchronous operation modes.

53.4.3.1 Physical Layer

A logical 1/0 is represented by data sync pulse of variable length, a logical 1 by the sync pulse of width W1(programmable from 0 to 127 μ s) and logical '0' by sync pulse with W0{programmable from 0 to 127 μ s}.

53.4.3.2 Data Link Layer

53.4.3.3 Bit coding

The bit period is the cycle time as specified for the operation mode, for example, 500 μ s in the PSI5-P10P-500/3L mode. (For details about this topology, please refer [Section 53.1.3.3.1, PSI5 topology](#).) The lower limit depends on the filter characteristics of the hardware circuitry used for the sync signal detection (subsequent sync signals might vary the internal $V_{ss, base}$ reference).

53.4.3.4 Data transmission

The IP supports the standard and the Non-Standard ECU to Sensor communication Formats. In the Non-Standard mode of communication it can be used to send any frame size programmable from 1-64 bits. The IP supports the PSI5 ECU to Sensor Communication formats as briefed below in [Figure 1188](#) and the text that follows it.

Figure 1188. Standard Frame Formats Supported

Frame 1, Short

Start				SAdr			FC				CRC			
0	1	0	S	A0	A1	A2	S	F0	F1	F2	S	C2	C1	C0

N° Bits: 15 (including start+stuff)

 Synchronization Bit [1]

Frame 2, Long (4-Bit Data Nibbles)

Start				SAdr			FC			RAdr						Data				CRC								
0	1	0	S	A0	A1	A2	S	F0	F1	F2	S	0	1	0	S	X3	X4	X5	S	D0	D1	D2	S	D3	C2	C1	S	C0

N° Bits: 29 (including start + stuff)

Frame 2, Long (8-Bit Data Word)

Start				SAdr			FC			RAdr		Data								CRC								
0	1	0	S	A0	A1	A2	S	F0	F1	F2	S	X0	X1	D0	S	D1	D2	D3	S	D4	D5	D6	S	D7	C2	C1	S	C0

N° Bits: 29 (including start+stuff)

Frame 3, XLong

Start				SAdr			FC			RAdr			Data			CRC					
0	1	0	S	A0	A1	A2	S	F0	F1	F2	S	X0 - X7 + Sync Bits			D0 - D7 + Sync Bits			C2	C1	S	C0

N° Bits: 37 (including start+stuff)

 Synchronization Bit [0]

 Configuration Bit
 [1] Mapping of frames 1-3
 [0] all other applications

Frame 4, XXLong

Start									SAdr				Data										CRC							
S	1	1	1	1	1	1	1	S	A0	A1	A2	C	D0	D1	S	D2	...	D7	S	D8 - D19 + Sync Bits				S	C0	C1	C2	C3	C4	C5

N° Bits: 43 (including start+stuff)

- Short:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "C2, C1, C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor

address, F0-F2 are the functional codes and "C2-C0" is the CRC. Please refer [Figure 1188](#) for the frame structure.

- The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of "111(C2:C0)".
- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[5],000) with DPR[0] being fed first in the CRC calculator.
